IMPORTANT NOTICE

Texas Instruments and its subsidiaries (TI) reserve the right to make changes to their products or to discontinue any product or service without notice, and advise customers to obtain the latest version of relevant information to verify, before placing orders, that information being relied on is current and complete. All products are sold subject to the terms and conditions of sale supplied at the time of order acknowledgement, including those pertaining to warranty, patent infringement, and limitation of liability.

TI warrants performance of its semiconductor products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

CERTAIN APPLICATIONS USING SEMICONDUCTOR PRODUCTS MAY INVOLVE POTENTIAL RISKS OF DEATH, PERSONAL INJURY, OR SEVERE PROPERTY OR ENVIRONMENTAL DAMAGE ("CRITICAL APPLICATIONS"). TI SEMICONDUCTOR PRODUCTS ARE NOT DESIGNED, AUTHORIZED, OR WARRANTED TO BE SUITABLE FOR USE IN LIFE-SUPPORT DEVICES OR SYSTEMS OR OTHER CRITICAL APPLICATIONS. INCLUSION OF TI PRODUCTS IN SUCH APPLICATIONS IS UNDERSTOOD TO BE FULLY AT THE CUSTOMER'S RISK.

In order to minimize risks associated with the customer's applications, adequate design and operating safeguards must be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance or customer product design. TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used. TI's publication of information regarding any third party's products or services does not constitute TI's approval, warranty or endorsement thereof.

About This Manual

This book is an introduction to the TMS320C6000 platform of digital signal processor (DSP) devices. This book describes the CPU architecture, peripherals, and development tools for the TMS320C6000 DSPs. Unless otherwise specified, all references to the ’C6000 refer to the TMS320C6000 platform of DSPs, ’C62x refers to the TMS320C62x fixed-point DSPs in the ’C6000 platform, and ’C67x refers to the TMS320C67x floating-point DSPs in the ’C6000 platform.

How to Use This Manual

The following table summarizes the information in this technical brief:

If you are looking for information about:	Turn to these chapters:
Code generation tools	Chapter 5, *Development Support*
CPU architecture	Chapter 2, *CPU Architecture*
Development support tools	Chapter 5, *Development Support*
Direct-memory access (DMA)	Chapter 4, *Peripherals*
Evaluation tools	Chapter 5, *Development Support*
External memory interface	Chapter 3, *Memory* Chapter 4, *Peripherals*
Host-port interface	Chapter 4, *Peripherals*
Memory map	Chapter 3, *Memory*
Multichannel buffered serial port (McBSP)	Chapter 4, *Peripherals*
Peripherals	Chapter 4, *Peripherals*
Timers	Chapter 4, *Peripherals*

Related Documentation From Texas Instruments

The following books describe the TMS320C62x/C67x devices and related support tools. To obtain a copy of any of these TI documents, call the Texas Instruments Literature Response Center at (800) 477–8924. When ordering, please identify the book by its title and literature number.

TMS320C6201 Digital Signal Processor Data Sheet (literature number SPRS051) describes the features of the TMS320C6201 and provides pinouts, electrical specifications, and timings for the device.

TMS320C6202 Digital Signal Processor Data Sheet (literature number SPRS072) describes the features of the TMS320C6202 and provides pinouts, electrical specifications, and timings for the device.

TMS320C6211 Digital Signal Processor Data Sheet (literature number SPRS073) describes the features of the TMS320C6211 and provides pinouts, electrical specifications, and timings for the device.

TMS320C6701 Digital Signal Processor Data Sheet (literature number SPRS067) describes the features of the TMS320C6701 and provides pinouts, electrical specifications, and timings for the device.

TMS320C62x/C67x CPU and Instruction Set Reference Guide (literature number SPRU189) describes the 'C62x/C67x CPU architecture, instruction set, pipeline, and interrupts for these digital signal processors.

TMS320C6201/C6701 Peripherals Reference Guide (literature number SPRU190) describes common peripherals available on the TMS320C6201/C6701 digital signal processors. This book includes information on the internal data and program memories, the external memory interface (EMIF), the host port, multichannel buffered serial ports, direct memory access (DMA), clocking and phase-locked loop (PLL), and the power-down modes.

TMS320C6202/C6211 Peripheral Addendum to the TMS320C6201/C6701 Peripherals Reference Guide (literature number SPRU290) describes common peripherals available on the TMS320C6202/C6211 digital signal processors. This book includes information on the internal data and program memories, the external memory interface (EMIF), the host port, multichannel buffered serial ports, direct memory access (DMA), clocking and phase-locked loop (PLL), and the power-down modes.

TMS320C62x/C67x Programmer's Guide (literature number SPRU198) describes ways to optimize C and assembly code for the TMS320C62x/C67x DSPs and includes application program examples.

TMS320C6x Assembly Language Tools User's Guide (literature number SPRU186) describes the assembly language tools (assembler, linker, and other tools used to develop assembly language code), assembler directives, macros, common object file format, and symbolic debugging directives for the 'C6x generation of devices.

TMS320C6x Optimizing C Compiler User's Guide (literature number SPRU187) describes the 'C6x C compiler and the assembly optimizer. This C compiler accepts ANSI standard C source code and produces assembly language source code for the 'C6x generation of devices. The assembly optimizer helps you optimize your assembly code.

TMS320C6x C Source Debugger User's Guide (literature number SPRU188) tells you how to invoke the 'C6x simulator and emulator versions of the C source debugger interface. This book discusses various aspects of the debugger, including command entry, code execution, data management, breakpoints, profiling, and analysis.

TMS320 DSP Development Support Reference Guide (literature number SPRU011) describes the TMS320 family of digital signal processors and the tools that support these devices. Included are code-generation tools (compilers, assemblers, linkers, etc.) and system integration and debug tools (simulators, emulators, evaluation modules, etc.). Also covered are available documentation, seminars, the university program, and factory repair and exchange.

Chapter 1

Introduction

The TMS320C6000 platform of digital signal processors (DSPs) is part of the TMS320 family of DSPs. The TMS320C62x (’C62x) devices are fixed-point DSPs in the TMS320C6000 platform. The TMS320C67x (’C67x) devices are floating-point DSPs in the TMS320C6000 platform.

The TMS320C62x and TMS320C67x are code compatible and both feature the VelociTI™ architecture. The VelociTI architecture is a high-performance, advanced, very-long-instruction-word (VLIW) architecture developed by Texas Instruments, making these DSPs excellent choices for multichannel and multifunction applications. VelociTI, together with the development tool set and evaluation tools, provides faster development time and higher performance for embedded DSP applications through increased instruction-level parallelism.

Topic **Page**

1.1 The TMS320 Family of Digital Signal Processors

The TMS320 family consists of 16-bit and 32-bit fixed- and floating-point devices. These DSPs possess the operational flexibility of high-speed controllers and the numerical capability of array processors. The following characteristics make this family the ideal choice for a wide range of processing applications:

- Very flexible instruction set
- Inherent operational flexibility
- High-speed performance
- Innovative, parallel architectural design
- Cost-effectiveness

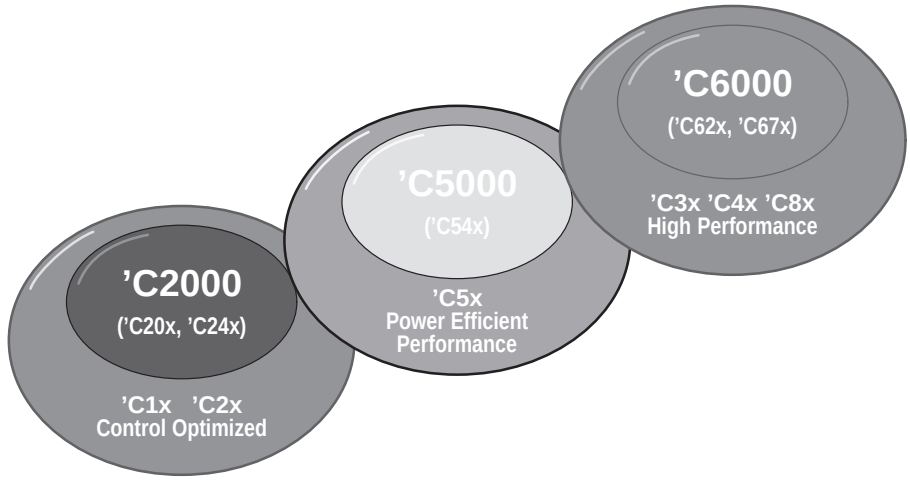
1.1.1 History, Development, and Advantages of TMS320 DSPs

In 1982, Texas Instruments introduced the TMS32010 — the first fixed-point DSP in the TMS320 family. Before the end of the year, the *Electronic Products* magazine awarded the TMS32010 the title “Product of the Year”. The TMS32010 became the model for future TMS320 generations.

Today, the TMS320 family consists of three supported platforms including the TMS320C2000, TMS320C5000, and TMS320C6000. Within the ’C6000 platform there are two generations, the TMS320C62x and TMS320C67x, with performance and features that are reflective of Texas Instruments’ commitment to lead the world in DSP solutions.

Each generation of TMS320 devices uses a core central processing unit (CPU) that is combined with a variety of on-chip memory and peripheral configurations. These various configurations satisfy a wide range of needs in the worldwide electronics market. When memory and peripherals are integrated with a CPU into one chip, the overall system cost is greatly reduced, and circuit board space is reduced. Figure 1–1 shows the progression of the TMS320 family of devices.

Figure 1–1. The TMS320 Family of Digital Signal Processors (DSPs)



1.1.2 Typical Applications for the TMS320 Family

The TMS320 family of DSPs offers adaptable approaches to traditional signal-processing problems, such as vocoding, filtering, and error coding. Furthermore, the TMS320 family supports complex applications that often require multiple operations to be performed simultaneously. Table 1–1 lists many of the typical applications of the TMS320 family.

Table 1–1. Typical Applications for the TMS320 Family of Digital Signal Processors (DSPs)

Automotive	Consumer	Control
Adaptive ride control	Digital radios/TVs	Disk drive control
Antiskid brakes	Educational toys	Engine control
Cellular telephones	Music synthesizers	Laser printer control
Digital radios	Pagers	Motor control
Engine control	Power tools	Robotics control
Global positioning	Radar detectors	Servo control
Navigation	Solid-state answering machines	
Vibration analysis		
Voice commands		
General-Purpose	**Graphics/Imaging**	**Industrial**
Adaptive filtering	3-D computing	Numeric control
Convolution	Animation/digital maps	Power-line monitoring
Correlation	Homomorphic processing	Robotics
Digital filtering	Image compression/transmission	Security access
Fast Fourier transforms	Image enhancement	
Hilbert transforms	Pattern recognition	
Waveform generation	Robot vision	
Windowing	Workstations	
Instrumentation	**Medical**	**Military**
Digital filtering	Diagnostic equipment	Image processing
Function generation	Fetal monitoring	Missile guidance
Pattern matching	Hearing aids	Navigation
Phase-locked loops	Patient monitoring	Radar processing
Seismic processing	Prosthetics	Radio frequency modems
Spectrum analysis	Ultrasound equipment	Secure communications
Transient analysis		Sonar processing
Telecommunications		**Voice/Speech**
1200- to 56 600-bps modems	Faxing	Speaker verification
Adaptive equalizers	Future terminals	Speech enhancement
ADPCM transcoders	Line repeaters	Speech recognition
Base stations	Personal communications systems (PCS)	Speech synthesis
Cellular telephones	Personal digital assistants (PDA)	Speech vocoding
Channel multiplexing	Speaker phones	Text-to-speech
Data encryption	Spread spectrum communications	Voice mail
Digital PBXs	Digital subscriber loop (xDSL)	
Digital speech interpolation (DSI)	Video conferencing	
DTMF encoding/decoding	X.25 packet switching	
Echo cancellation		

1.2 Introduction to the TMS320C6000 Platform of Digital Signal Processors

With performance of up to 2000 million instructions per second (MIPS) at 250 MHz and a complete set of development tools, the TMS320C6000 DSPs offer cost-effective solutions to high-performance DSP programming challenges. The TMS320C6000 development tools include a new C compiler, an assembly optimizer that simplifies programming and scheduling, and a Windows™ debugger interface.

The TMS320C6000 DSPs give system architects unlimited possibilities to differentiate their products. High performance, ease of use, and affordable pricing make the TMS320C6000 platform the ideal solution for multichannel, multifunction applications, such as:

- Pooled modems
- Wireless local loop base stations
- Beam-forming base stations
- Remote access servers (RAS)
- Digital subscriber loop (DSL) systems
- Cable modems
- Multichannel telephony systems
- Virtual reality 3-D graphics
- Speech recognition
- Audio
- Radar
- Atmospheric modeling
- Finite element analysis
- Imaging (examples: fingerprint recognition, ultrasound, and MRI)

The TMS320C6000 platform is also an ideal solution for exciting new applications; for example:

- Personalized home security with face and hand/fingerprint recognition
- Advanced cruise control with global positioning systems (GPS) navigation and accident avoidance
- Remote medical diagnostics

1.3 Features and Options of the TMS320C62x/C67x Devices

The ’C6211, ’C6701, ’C6201, and ’C6202 devices operate at 150, 167, 200, and 250 MHz respectively (6.67-, 6-, 5-, and 4-ns cycle times). All of these DSPs execute up to eight 32-bit instructions every cycle. The core CPU consists of 32 general-purpose registers of 32-bit word length and eight functional units:

- Two multipliers
- Six ALUs

The ’C62x/C67x devices have a complete set of optimized development tools, including an efficient C compiler, an assembly optimizer for simplified assembly-language programming and scheduling, and a Windows-based debugger interface for visibility into source code execution characteristics. A hardware emulation board, compatible with the TI XDS510™ emulator interface, is also available. This tool complies with IEEE Standard 1149.1–1990, IEEE Standard Test Access Port and Boundary-Scan Architecture.

Features of the ’C62x/C67x include:

- Advanced VLIW CPU with eight functional units, including two multipliers and six arithmetic units
  - Executes up to eight instructions per cycle for up to ten times the performance of typical DSPs
  - Allows designers to develop highly effective RISC-like code for fast development time
- Instruction packing
  - Gives code size equivalence for eight instructions executed serially or in parallel
  - Reduces code size, program fetches, and power consumption
- All instructions execute conditionally.
  - Reduces costly branching
  - Increases parallelism for higher sustained performance
- Code executes as programmed on independent functional units.
  - Industry’s most efficient C compiler on DSP benchmark suite
  - Industry’s first assembly optimizer for fast development and improved parallelization
- 8/16/32-bit data support, providing efficient memory support for a variety of applications

- 40-bit arithmetic options that add extra precision for vocoders and other computationally intensive applications
- Saturation and normalization provide support for key arithmetic operations.
- Field manipulation and instruction extract, set, clear, and bit counting support common operation found in control and data manipulation applications.

The ’C67x has the following features:

- Peak 1336 MIPS at 167 MHz
- Peak 1G FLOPS at 167 MHz for single-precision operations
- Peak 250M FLOPS at 167 MHz for double-precision operations
- Peak 688M FLOPS at 167 MHz for multiply and accumulate operations
- Hardware support for single-precision (32-bit) and double-precision (64-bit) IEEE floating-point operations.
- 32 $\times$ 32-bit integer multiply with 32- or 64-bit result.

A variety of memory and peripheral options are available for the ’C62x/C67x:

- Large on-chip RAM for fast algorithm execution
- 32-bit external memory interface supports SDRAM, SBSRAM, SRAM, and other asynchronous memories, for a broad range of external memory requirements and maximum system performance
- Host port access to ’C62x/C67x memory and peripherals
- Multichannel DMA controller
- Multichannel serial port(s)
- 32-bit timer(s)

Chapter 2

CPU Architecture

The VelociTI architecture makes the ’C6000 DSPs the first off-the-shelf DSPs to use an enhancement of traditional VLIW to achieve high performance through increased instruction-level parallelism. A traditional VLIW architecture consists of multiple execution units running in parallel that perform multiple instructions during a single clock cycle. Parallelism is the key to extremely high performance and takes these next-generation DSPs well beyond the performance capabilities of traditional superscalar designs. VelociTI is a highly deterministic architecture, with few restrictions on how or when instructions are fetched, executed, or stored. This architectural flexibility is key to the breakthrough efficiency levels of the ’C6000 compiler.

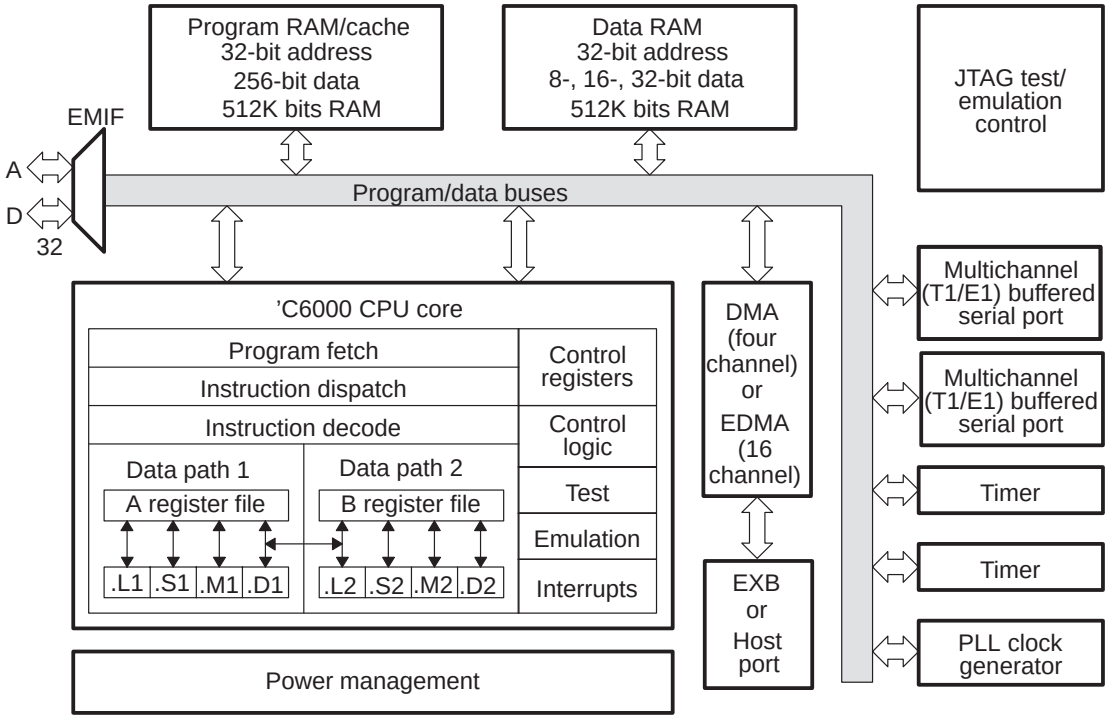
Topic **Page**

2.1 TMS320C62x/C67x Block Diagram

The ’C62x/C67x processor consists of three main parts: CPU (or the *core*), peripherals, and memory. Eight functional units operate in parallel, with two similar sets of the basic four functional units. The units communicate using a cross path between two register files, each of which contains 16 32-bit registers. Program parallelism is defined at compile time because there is no data dependency checking done in hardware during run time. The 256-bit-wide program memory fetches eight 32-bit instructions every single cycle.

Figure 2–1 is the block diagram for the TMS320C62x/C67x devices. The ’C62x/C67x devices come with on-chip program and data memory, which may be configured as cache on some devices. Peripherals include a direct memory access (DMA) controller, power-down logic, external memory interface (EMIF), serial port(s), expansion bus or host port, and timer(s). Check the data sheet for your device to determine the specific peripheral configurations you have.

Figure 2–1. TMS320C62x/C67x Block Diagram



2.2 Central Processing Unit (CPU)

The ’C62x/C67x CPU, in Figure 2–1, is common to all the ’C62x/C67x devices. The CPU contains:

- Program fetch unit
- Instruction dispatch unit
- Instruction decode unit
- 32 32-bit registers
- Two data paths, each with four functional units
- Control registers
- Control logic
- Test, emulation, and interrupt logic

The CPU has two data paths (A and B) in which processing occurs. Each data path has four functional units (.L, .S, .M, and .D) and a register file containing 16 32-bit registers. The functional units execute logic, shifting, multiply, and data address operations. All instructions except loads and stores operate on the registers. The two data-addressing units (.D1 and .D2) are exclusively responsible for all data transfers between the register files and memory.

The four functional units of a data path have a single data bus connected to registers on the other side of the CPU so that the units can exchange data with the register file on the opposite side. Register access across the CPU supports one read and write operation per cycle.

The two sets of functional units include the following items:

- Two multipliers
- Six arithmetic logic units (ALUs)
- Two register files, each containing 16 32-bit registers

Each functional unit is controlled by a 32-bit instruction. The instruction fetch, instruction dispatch, and instruction decode blocks can deliver up to eight 32-bit instructions from the program memory to the functional units every cycle. The control register file provides methods to configure and control various aspects of processor operation. Access to the control registers is provided from data-path B.

The VLIW processing flow begins when a 256-bit-wide instruction fetch packet (IFP) is fetched from the internal program memory. The instructions linked together for simultaneous execution (up to eight instructions) form an execute packet. For more details on the processing, see the data sheet for your particular device.

2.3 CPU Data Paths

Figure 2–2 shows the ’C62x CPU data paths and Figure 2–3 shows the ’C67x CPU data paths, which consist of:

- Two general-purpose register files (A and B)
- Eight functional units (.L1, .L2, .S1, .S2, .M1, .M2, .D1, and .D2)
- Two load-from-memory paths (LD1 and LD2)
- Two store-to-memory paths (ST1 and ST2)
- Two register file cross paths (1X and 2X)
- Two data address paths (DA1 and DA2)

2.3.1 General-Purpose Register Files

There are two general-purpose register files (A and B) in the ’C62x/C67x data paths. Each of these files contains 16 32-bit registers (A0–A15 for file A and B0–B15 for file B). The general-purpose registers can be used for data or data-address pointers. Registers A1, A2, B0, B1, and B2 can be used for condition registers. Registers A4–A7 and B4–B7 can be used for circular addressing.

The general-purpose register files support 32- and 40-bit fixed-point data. 32-bit data can be contained in any general-purpose register. 40-bit data is contained across two registers; the 32 LSBs of the data are placed in an even register and the remaining eight MSBs are placed in the eight LSBs of the next upper register (which is always an odd register). The ’C67x also uses these register pairs to hold 64-bit double-precision floating-point values.

Figure 2–2. TMS320C62x CPU Data Paths

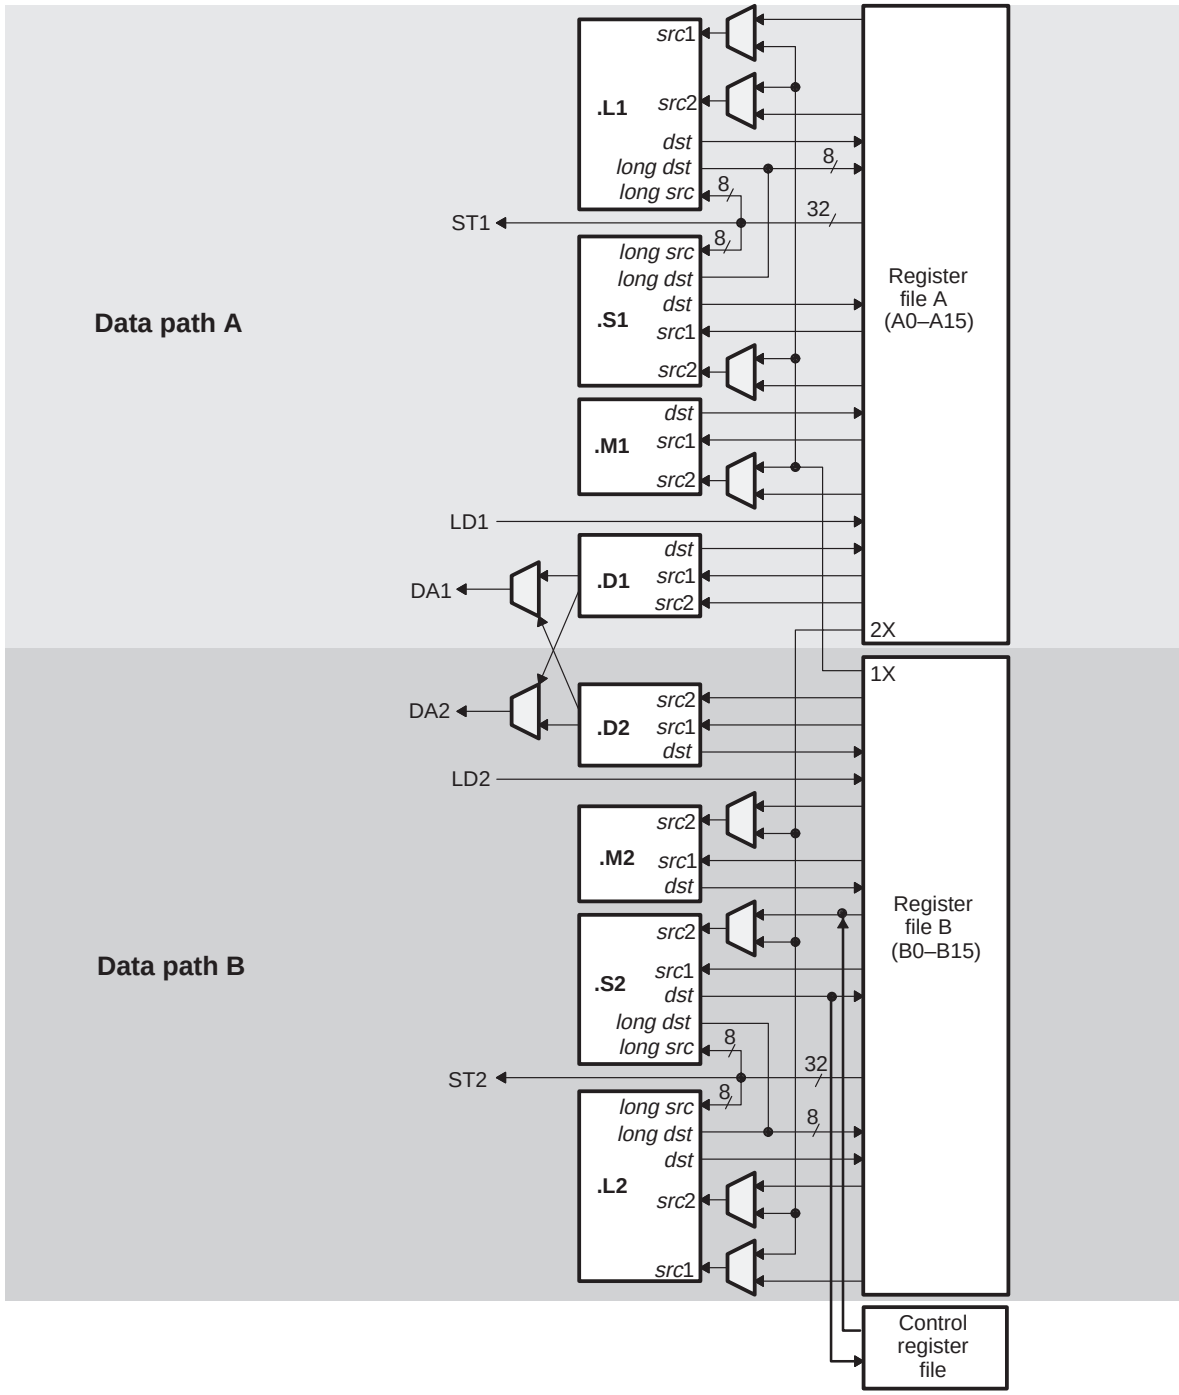


Figure 2–3. TMS320C67x CPU and Data Paths

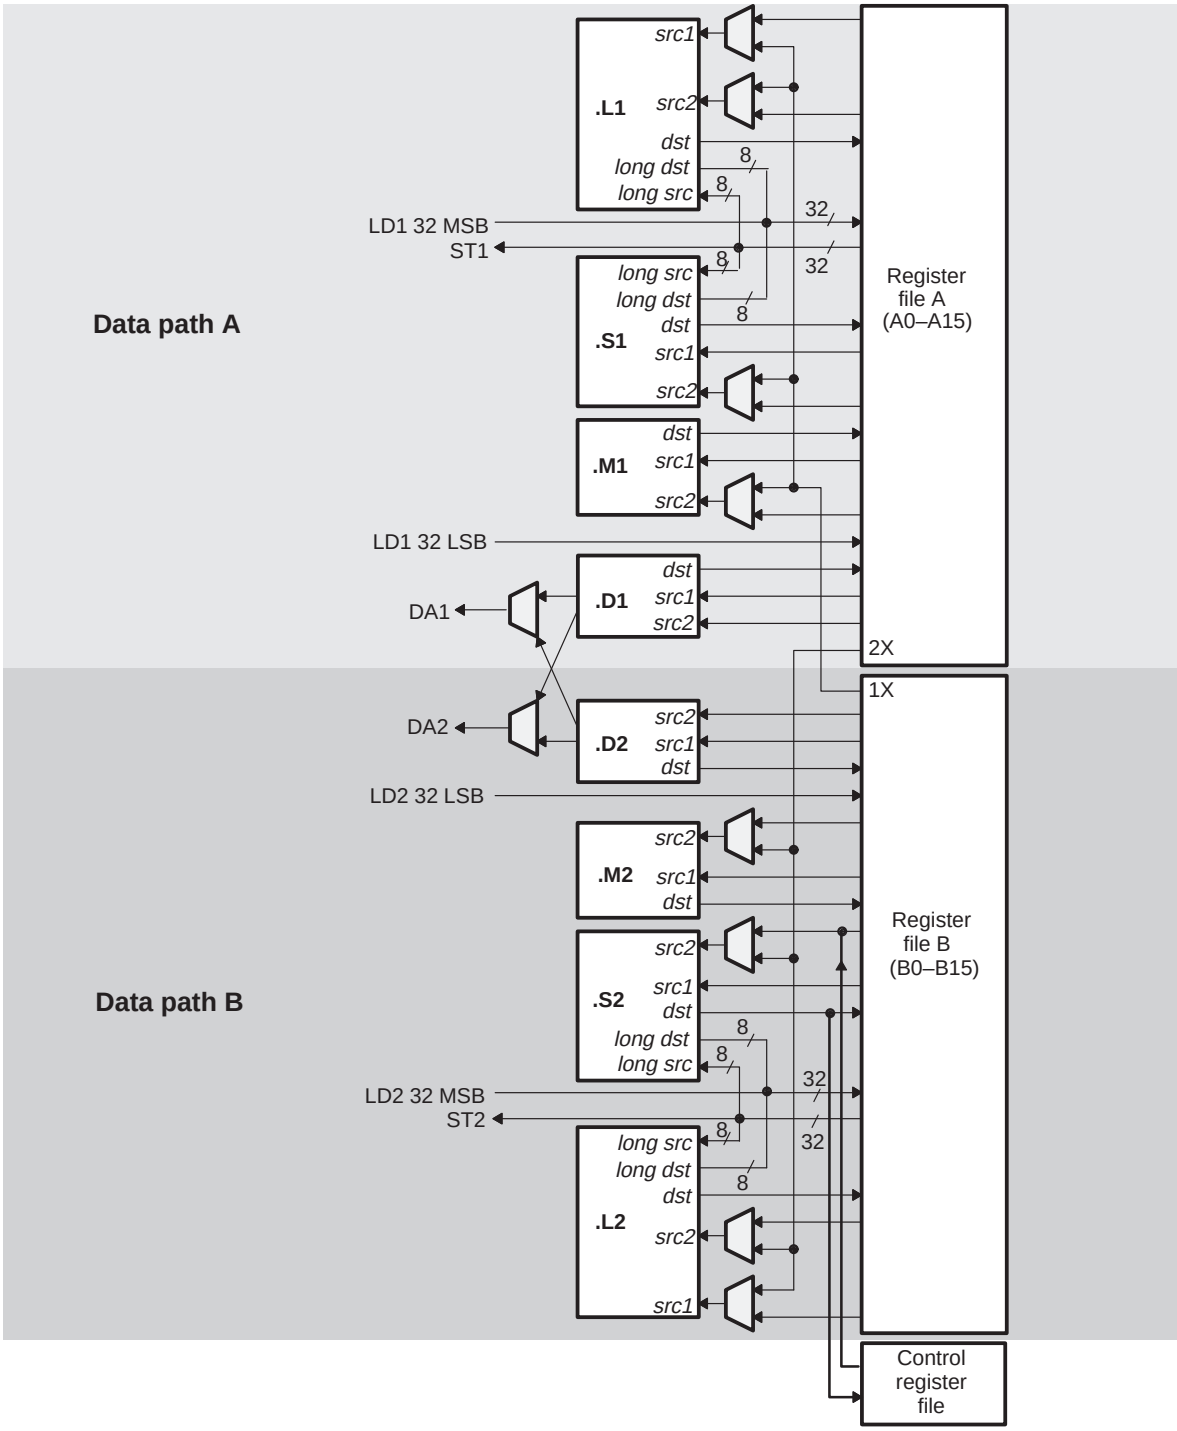

2.3.2 Functional Units

The eight functional units in the ’C62x/C67x data paths can be divided into two groups of four; each functional unit in one data path is almost identical to the corresponding unit in the other data path. The functional units are described in Table 2–1.

Most data lines in the CPU support 32-bit operands, and some support long (40-bit) operands. Each functional unit has its own 32-bit write port into a general-purpose register file. All units ending in 1 (for example, .L1) write to register file A and all units ending in 2 write to register file B. Each functional unit has two 32-bit read ports for source operands *src1* and *src2*. Four units (.L1, .L2, .S1, and .S2) have an extra 8-bit-wide port for 40-bit long writes as well as an 8-bit input for 40-bit long reads. Because each unit has its own 32-bit write port, all eight units can be used in parallel every cycle.

Table 2–1. Functional Units and Operations Performed

Functional Unit	Fixed-Point Operations	Floating-Point Operations
.L unit (.L1,.L2)	32/40-bit arithmetic and compare operations Leftmost 1 or 0 bit counting for 32 bits Normalization count for 32 and 40 bits 32-bit logical operations	Arithmetic operations Conversion operations: DP $\rightarrow$ SP, INT $\rightarrow$ DP, INT $\rightarrow$ SP
.S unit (.S1, .S2)	32-bit arithmetic operations 32/40-bit shifts and 32-bit bit-field operations 32-bit logical operations Branches Constant generation Register transfers to/from the control register file (.S2 only)	Compare reciprocal and reciprocal square-root operations Absolute value operations SP to DP conversion operations
.M unit (.M1, .M2)	16 $\times$ 16 bit multiply operations	32 $\times$ 32 bit multiply operations Floating-point multiply operations
.D unit (.D1, .D2)	32-bit add, subtract, linear and circular address calculation Loads and stores with a 5-bit constant offset Loads and stores with a 15-bit constant offset (.D2 only)	Load double word with a 5-bit constant offset

2.3.3 TMS320C62x/C67x Control Register Files

One unit (.S2) can read from and write to the control register file, shown in Figure 2–2 and Figure 2–3. Table 2–2 lists the control registers contained in the control register file and describes each. Each control register is accessed by the MVC instruction.

Table 2–2. Control Registers

Register		
Abbreviation	**Name**	**Description**
AMR	Addressing mode register	Specifies whether to use linear or circular addressing for each of eight registers; also contains sizes for circular addressing
CSR	Control status register	Contains the global interrupt enable bit, cache control bits, and other miscellaneous control and status bits
IFR	Interrupt flag register	Displays status of interrupts
ISR	Interrupt set register	Allows you to set pending interrupts manually
ICR	Interrupt clear register	Allows you to clear pending interrupts manually
IER	Interrupt enable register	Allows enabling/disabling of individual interrupts
ISTP	Interrupt service table pointer	Points to the beginning of the interrupt service table
IRP	Interrupt return pointer	Contains the address to be used to return from a maskable interrupt
NRP	Nonmaskable interrupt return pointer	Contains the address to be used to return from a nonmaskable interrupt
PCE1	Program counter, E1 phase	Contains the address of the fetch packet that contains the execute packet in the E1 pipeline stage

2.3.4 TMS320C67x Control Register File Extensions

The ’C67x has three additional configuration registers to support floating point operations (see Table 2–3). The registers specify the desired floating-point rounding mode for the .L and .M units. They also contain bit fields to warn if *src1* and *src2* are NaN (not a number) or denormal numbers, and if the result overflows, underflows, is inexact, infinite, or invalid. There are also fields to warn if a divide by 0 was performed, or if a compare was attempted with a NaN source.

Table 2–3. TMS320C67x Control Register File Extensions

Register		
Abbreviation	**Name**	**Description**
FADCR	Floating-point adder configuration register	Specifies underflow mode, rounding mode, NaNs, and other exceptions for the .L unit.
FAUCR	Floating-point auxiliary configuration register	Specifies underflow mode, rounding mode, NaNs, and other exceptions for the .S unit.
FMCR	Floating-point multiplier configuration register	Specifies underflow mode, rounding mode, NaNs, and other exceptions for the .M unit.

2.3.5 Register File Cross Paths

Each functional unit reads directly from and writes directly to the register file within its own data path. That is, the .L1, .S1, .D1, and .M1 units write to register file A and the .L2, .S2, .D2, and .M2 units write to register file B. The register files are connected to the opposite-side register file’s functional units via the 1X and 2X cross paths. These cross paths allow functional units from one data path to access a 32-bit operand from the opposite side’s register file. The 1X cross path allows data path A’s functional units to read their source from register file B and the 2X cross path allows data path B’s functional units to read their source from register file A.

Six of the functional units have access to the opposite side’s register file via a cross path. The .M1, .M2, .S1, and .S2 units’ *src2* inputs are multiplex-selectable between the cross path and the same side register file. The .L1 and .L2 units’ *src1* and *src2* inputs are also multiplex-selectable between the cross path and the same side register file.

Only two cross paths, 1X and 2X, exist in the ’C62x/C67x CPUs. This limits one source read from each data path’s opposite register file per cycle, or two cross-path source reads per cycle.

2.3.6 Memory, Load, and Store Paths

There are two 32-bit paths for loading data from memory to the register file: LD1 for register file A, and LD2 for register file B. The ’C67x also has a second 32-bit load path for both register files A and B, which allows the LDDW instruction to simultaneously load two 32-bit registers into side A and two 32-bit registers into side B. There are also two 32-bit paths, ST1 and ST2, for storing register values to memory from each register file. The store paths are shared with the .L and .S long read paths.

2.3.7 Data-Address Paths

The data-address paths (DA1 and DA2) shown in Figure 2–2 and Figure 2–3 coming out of the .D units allow data addresses generated from one register file to support loads and stores to memory from the other register file. However, loads and stores executed in parallel must load to and from the same register file or both use a crosspath to the opposite register.

2.4 Mapping Between Instructions and Functional Units

Table 2–4 shows the mapping between instructions and functional units and Table 2–5 shows the mapping between functional units and instructions for the TMS320C62x/C67x fixed-point instructions.

2.5 Addressing Modes

The addressing modes on the ’C62x and ’C67x are linear by default, but circular addressing is available. The mode is specified by the addressing mode register (AMR).

All registers can perform linear addressing. Only eight registers can perform circular addressing: A4–A7 are used by the .D1 unit and B4–B7 are used by the .D2 unit. No other units can perform circular addressing. **LDB/LDH/LDW**, **STB/STH/STW**, **ADDAB/ADDAH/ADDAW**, and **SUBAB/SUBAH/SUBAW** instructions all use the AMR to determine what type of address calculations are performed for these registers.

The ’C62x/C67x CPU has a load/store architecture, which means that the only way to access data in memory is with a load or store instruction. Table 2–8 shows the syntax of an indirect address to a memory location.

Table 2–8. Indirect Address Generation for Load/Store

Addressing Type	No Modification of Address Register	Preincrement or Predecrement of Address Register	Postincrement or Postdecrement of Address Register
Register indirect	*R	*++R *– –R	*R++ *R– –
Register relative	*+R[*ucst5*] *–R[*ucst5*]	*+ +R[*ucst5*] *– –R[*ucst5*]	*R+ +[*ucst5*] *R– –[*ucst5*]
Base + index	*+R[*offsetR*] *–R[*offsetR*]	*+ +R[*offsetR*] *– –R[*offsetR*]	*R+ +[*offsetR*] *R– –[*offsetR*]

For more information on addressing modes, see the *TMS320C62x/C67x CPU and Instruction Set Reference Guide*.

2.6 Interrupts

The ’C62x/C67x CPU has 14 interrupts. These are reset, the nonmaskable interrupt (NMI), and interrupts 4–15. These interrupts correspond to the $\overline{\text{RESET}}$, NMI, and INT4–INT15 signals on the CPU boundary. In some ’C62x/C67x devices, these signals may be tied directly to pins on the device, connected to on-chip peripherals, or may be disabled permanently by being tied inactive on chip. Generally, $\overline{\text{RESET}}$ and NMI are connected directly to pins on the device. Characteristics of interrupt servicing include:

- The IACK pin from the CPU is used to acknowledge an interrupt request.
- The INUM0–INUM3 pins indicate which interrupt vector is being serviced.
- Interrupt vectors are relocatable.
- Interrupt vectors consist of one fetch packet which provides for quick servicing.

For more information on interrupts, see the *TMS320C62x/C67x CPU and Instruction Set Reference Guide,* the *TMS320C6201/C6701 Peripherals Reference Guide,* and the *TMS320C6202/C6211 Peripherals Reference Guide Addendum*.

Chapter 3

Memory

The TMS320C6000 platform of devices includes on-chip memory for both program and data, some of which may be selected as cache. In addition, an external memory interface (EMIF) may be used to include external memories in a ’C6000 system.

Topic **Page**

3.1 Memory Maps

The memory maps of the ’C6000 platform of devices are shown in Figure 3–1 and Figure 3–2. The total memory address range of the ’C6000 devices is 4Gbytes (corresponding to 32-bit internal address representation). Each memory map is divided into the internal program memory, internal data memory, external memory spaces, and internal peripheral space.

Figure 3–1. TMS320C6201/C6202/C6701 Memory Maps

Starting address	Memory map 0 (Direct execution)	Block size (bytes)	Starting address	Memory map 1 (Boot mode)	Block size (bytes)
0000 0000h	External memory space CE0	16M	0000 0000h	Internal program RAM	64K/(256K on ’C6202)

8001 0000h 8002 0000h	Reserved	2G–64K (2G–128K on ’C6202)	8001 0000h 8002 0000h	Reserved	2G–64K (2G–128K on ’C6202)

Figure 3–2. TMS320C6211 Memory Map

Starting Address	Memory Block	Block Size (Bytes)
0000 0000h	Internal RAM (L2)	64K
0001 0000h	Reserved	24M–64K
0180 0000h	Configuration and peripherals	8M
0200 0000h	Reserved	224M
1000 0000h	External memory	512M
3000 0000h	Reserved	256M
4000 0000h	McBSP 0/1 Data	256M
5000 0000h	Reserved	256M
6000 0000h	HPI expansion bus	256M
7000 0000h	Reserved	2G + 256M

For the ’C6201 and ’C6701, five BOOTMODE pins determine which memory map and boot process are used.The ’C6202 has these five pins removed, and instead latches the expansion bus data lines XD[4:0] on the rising edge of $\overline{\text{RESET}}$. These pins should be pulled high or low through resistors to select the boot process and memory map. The ’C6211 has only one memory map, but selects the boot process in similar fashion to the ’C6202. HD[4:3] are sampled from the host-port interface on the rising edge of $\overline{\text{RESET}}$ to determine which boot process will be used.

The two modes of operation for these devices are direct execution and boot mode. In direct execution, the program starts loading from external address 0, whereas in boot mode, the program is loaded either from external memory or from an external host before starting execution at internal address 0.

3.2 Internal Memory

The amount and location of internal memory depends on the particular device. The ’C6201, ’C6202, and ’C6701 have separate program and data memories (Harvard architecture), while the ’C6211 has a portion of its internal memory that may be used for either program or data. Table 3–1 shows the internal memory configurations of the ’C6000 devices. Descriptions of the different cache architectures are given in Table 3–2.

Table 3–1. TMS320C6000 Internal Memory Configurations

Device	CPU	Internal Memory Architecture	Total Memory (Bytes)	Program Memory (Bytes)	Data Memory (Bytes)	Unified Memory (Bytes)
’C6201	6200	Harvard	128K	64K (map/cache)	64K (map)	None
’C6701	6700	Harvard	128K	64K (map/cache)	64K (map)	None
’C6202	6200	Harvard	384K	128K (map) 128K (map/cache)	128K (map)	None
’C6211	6200	Harvard (L1) Unified (L2)	72K	4K (cache)	4K (cache)	64K (map/cache)

Table 3–2. TMS320C6000 Cache Architectures

Cache Space	Size (Bytes)	Associativity	Line Size (Bytes)
’C6201 program	64K	Direct mapped	32
’C6701 program	64K	Direct mapped	32
’C6202 program	128K	Direct mapped	32
’C6211 L1P	4K	Direct mapped	64
’C6211 L1D	4K	2-way	32
’C6211 L2	64K	1- to 4-way	128

3.2.1 TMS320C6201 (Revision 2)

The TMS320C6201 has 64K bytes of internal program memory and 64K bytes of internal data memory. The program memory space may be selected as a program cache, to be used while running from an external memory space. The program memory is 256 bits wide, having one fetch packet per line. On each cache miss, one line is fetched from external memory.

The internal data memory is made up of four 16-bit wide banks. The DMA or CPU may access each bank once per cycle, and multiple banks may be accessed in the same cycle. Since the CPU has two sides (A and B), the data memory may be accessed by the CPU and DMA up to three times each cycle.

3.2.2 TMS320C6201B (Revision 3)

The TMS320C6201B has 64K bytes of internal program memory and 64K bytes of internal data memory, like the ’C6201. The program memory space is identical, and may be selected as a program cache. The program memory is 256 bytes wide, having one fetch packet per line. On each cache miss, one line is fetched from external memory.

The internal data memory is slightly different, modified to maximize the data accesses that may be performed each cycle by the three possible sources. Instead of four banks, the ’C6201B is made up of eight 16-bit wide banks. These are divided into two blocks of four banks, with the first four in the lower half of data memory, and the last four in the upper half. The DMA or CPU may access each bank once per cycle, and multiple banks may be accessed in the same cycle. With this memory configuration, the maximum data access each cycle is three 32-bit accesses; two CPU accesses and one DMA access.

3.2.3 TMS320C6701

The TMS320C6701 memory configuration is almost identical to that of the ’C6201B. It also has 64K bytes of internal program memory and 64K bytes of internal data memory, and the program may be selected as a program cache. The program memory line size is 32 bytes, having one fetch packet per line. On each cache miss, one line is fetched from external memory.

The internal data memory consists of two blocks of eight 16-bit banks, rather than four 16-bit banks. This feature allows parallel double-precision loads by the CPU in the same cycle as a data access by the DMA. With the new memory configuration, the maximum data access each cycle is two 64-bit CPU accesses (LDDW only) and 32-bit DMA access.

3.2.4 TMS320C6202

The TMS320C6202 has 256K bytes of internal program memory and 128K bytes of internal data memory. The program memory space consists of two 128K-byte banks, with one bank selectable as a program cache. This can effectively provide 128K bytes of program memory and 128K bytes of program cache, if selected. The program memory line size is 32 bytes, having one fetch packet per line. On each cache miss, one line is fetched from external memory.

The internal data memory is configured identically to the ’C6201B, with eight 16-bit wide banks. These are divided into two blocks of four banks, with the first four in the lower half of data memory, and the last four in the upper half. The DMA or CPU may access each bank once per cycle, and multiple banks may be accessed in the same cycle. With this memory configuration, the maximum data access is three 32-bit accesses.

3.2.5 TMS320C6211

The TMS320C6211 has a 4K-byte level-one program cache (L1P) and 4K-byte level-one data cache (L1D). These cache memories are always active and are not included in the memory map. The L1P line size is 64 bytes (two fetch packets), while the L1D line size is 32 bytes (eight data words). On a miss to either cache space, the entire line of the miss is fetched. For the instruction cache, this provides one pre-fetched instruction packet, while the data fetch will receive adjacent data elements. The level-one caches are transparent to the user.

The internal memory at address 0 is a unified 64K-byte data and instruction RAM. This memory may be configured in one of five modes to provide a level-two cache (both instruction and data), as shown in Table 3–3. The L2 SRAM space always begins at address zero, regardless of the cache mode selected. The length will vary.

Table 3–3. L2 Operation Modes

L2 Mode	Cache Size	SRAM size
000	0K	64K
001	16K 1-way	48K
010	32K 2-way	32K
011	48K 3-way	16K
100	Reserved	
101	Reserved	
110	Reserved	
111	64K 4-way	0K

The L2 memory is made up of four 64-bit-wide banks. On an L2 miss, 128 bytes of new data will be requested of the EDMA. The data is always aligned on a 32-word boundary.

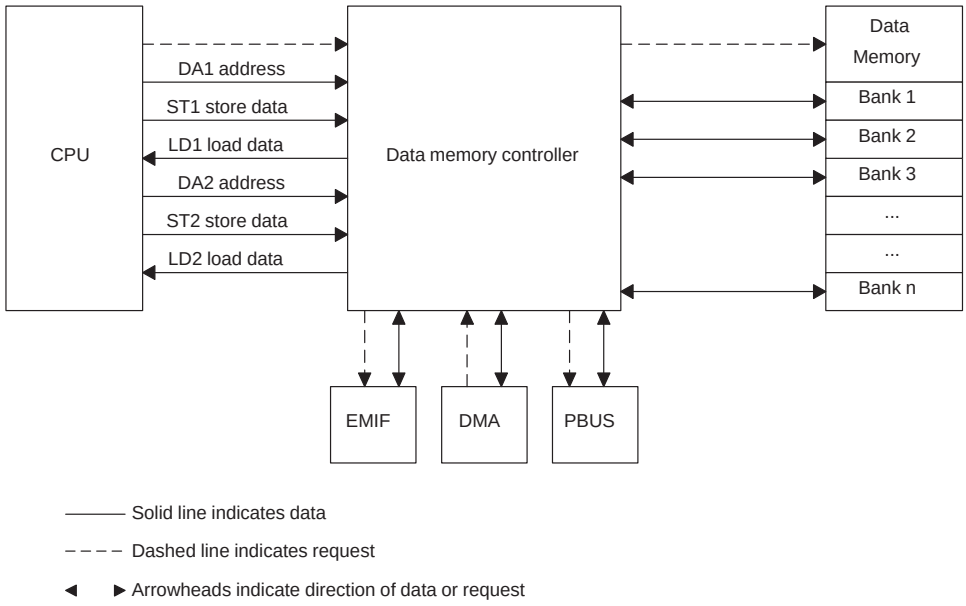
3.2.6 Data Memory Access

For the ’C6201, ’C6202, and ’C6701 the data memory controller services all requests to internal data memory by either the CPU or DMA. The ’C6211 has a level-one data cache (L1D) controller and a level-two cache (L2) controller. The L1D controller services the requests by the CPU and sends them to the L2 controller on a read or a write miss. Data requests by the EDMA go directly to the L2 controller.

3.2.7 TMS320C6201, ’C6202, ’C6701

The CPU sends requests to the data memory controller through the two address buses (DA1 and DA2). The data to be stored is transmitted through the CPU data store buses (ST1 and ST2). Load data is received through the CPU data load buses (LD1 and LD2). The CPU data requests are mapped based on the requested data’s memory address range to the internal data memory, internal peripheral space (through the peripheral bus controller), or the external memory interface. The data memory controller also connects to the internal data memory and performs CPU/DMA arbitration for the on-chip data RAM. Figure 3–3 shows the CPU, data memory controller, and peripheral bus connections.

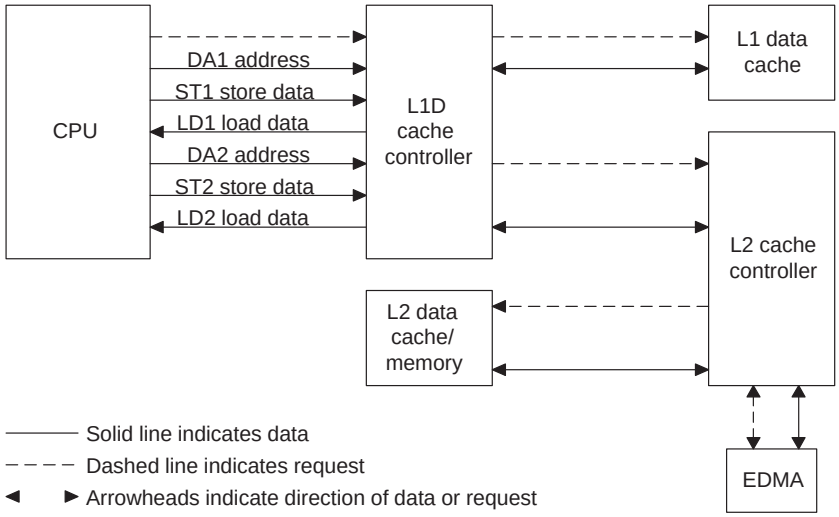
Figure 3–3. TMS320C6201/C6202/C6701 Data Memory Controller Interconnect



3.2.8 TMS320C6211

In the TMS320C6211, the CPU sends requests to the L1D controller in the same fashion as the ’C6201, ’C6202, and ’C6701 request data from the data memory controller. On a read data miss or a data write, the L1D controller sends a request to the L2 controller to complete the action. The L2 controller may then access the L2 cache/memory space, or send the request to the EDMA.

Figure 3–4. TMS320C6211 Data Memory Controller Interconnect



3.2.9 Peripheral Bus

The peripherals are configured via a set of memory-mapped control registers. The peripheral bus controller arbitrates all accesses to the control registers. On the ’C6201, ’C6202, and ’C6701, the DMA accesses the peripheral bus controller directly, while the CPU accesses it through the data memory controller.

On the ’C6211, the peripheral bus controller is incorporated into the L2 controller. The EDMA accesses this directly, while the CPU accesses it through the L1D controller.

The peripheral bus controller converts all peripheral bus accesses to word accesses. This affects all writes to a control register, as a byte or halfword will be treated as an unsigned 32-bit word. On reads, individual bytes may be accessed.

3.2.10 Expansion Bus

The expansion bus on the ’C6202 is a 32-bit-wide bus that supports a glueless synchronous FIFO interface, asynchronous interface, and two host modes. The two host modes are synchronous master/slave mode or asynchronous host mode. Mode selection is performed during boot using pull-up/down resistors. The expansion bus replaces the HPI and expands the memory options available to the user.

3.3 External Memory Interface (EMIF)

The external memory interface (EMIF) connects the CPU and external memory, such as synchronous dynamic RAM (SDRAM), synchronous burst static RAM (SBSRAM), and asynchronous memory. The EMIF also provides 8-bit-wide and 16-bit-wide memory read capability to support low-cost boot ROM memories (flash, EEPROM, EPROM, and PROM). The EMIF supports high throughput interfaces to SDRAM, including burst capability.

For more information on the EMIF, see section 4.5 of this book and the *TMS320C6000 Peripherals Reference Guide.* For more information on the expansion bus, see section 4.4. For more information on internal memory, see the *TMS320C6000 Peripherals Reference Guide*.

Chapter 4

Peripherals

In addition to on-chip memory, the TMS320C62x and TMS320C67x devices contain peripherals for communication with off-chip memory, coprocessors, host processors, and serial devices. These peripherals are briefly described here, but each ’C6000 device has only a specific subset of them. The peripherals available for each device in the ’C6000 platform are listed in Table 4–1. All peripherals are explained in detail in the *TMS320C6201/C6701 Peripherals User’s Guide* and/or the *TMS320C6202/C6211 Peripherals User’s Guide Addendum*.

Topic **Page**

Table 4–1. TMS320C6000 Peripherals

Device	EMIF	HPI	XB	McBSPs	Timers	PD Modes	Interrupt Select	External Interrupt
’C6201	✓	✓		2	2 (3)†	3	✓	4 (8)‡
’C6701	✓	✓		2	2 (3)†	3	✓	4 (8)‡
’C6202	✓		✓	2	2 (3)†	3	✓	4 (8)‡
’C6211	✓	✓		2	2 (3)†	3	✓	4 (8)‡

† If SDRAM is not used, the SDRAM refresh period timer may be used as a general purpose timer.
‡ If unused for serial port operation, the McBSP frame sync signals (FSX,FSR) on each McBSP may be configured as interrupts.

4.1 Direct Memory Access (DMA) Controller

Devices: ’C6201, ’C6202, and ’C6701

The direct memory access (DMA) controller transfers data between regions in the memory map without intervention by the CPU. The DMA allows movement of data to and from internal memory, internal peripherals, or external devices to occur in the background of CPU operation. The DMA has four independently programmable channels allowing four different contexts for operation. In addition, a fifth (auxiliary) channel allows the DMA to service requests from the host-port interface (HPI) or the Expansion Bus (XB). In discussing DMA operations, the following terms are important:

- **Read transfer:** The DMA reads the data element from a source location in memory.
- **Write transfer:** The DMA writes the data element that was read during a read transfer to its destination location in memory.
- **Element transfer:** The combined read and write transfer for a single data element.
- **Frame transfer:** Each DMA channel has an independently programmable number of elements per frame. In completing a frame transfer, the DMA moves all elements in a single frame.
- **Block transfer:** Each DMA channel also has an independently programmable number of frames per block. In completing a block transfer, the DMA moves all frames it has been programmed to move.

The DMA has the following features:

- **Background operation:** The DMA operates independently of the CPU.
- **High throughput:** Elements can be transferred at the CPU clock rate.
- **Four channels:** The DMA can keep track of the contexts of four independent block transfers.
- **Auxiliary channel:** This channel allows the host port to make requests into the CPU’s memory space. This chapter discusses how the auxiliary channel requests are prioritized relative to other channels and the CPU. Detailed explanation of how it is used in conjunction with a peripheral is found in that peripheral’s documentation.
- **Split operation:** A single channel may be used to simultaneously perform both the receive and transmit element transfers to or from two peripherals and memory, effectively acting like two DMAs.

- **Multi-frame transfer:** Each block transfer can consist of multiple frames of a programmable size.
- **Programmable priority:** Each channel has independently programmable priorities versus the CPU.
- **Programmable address generation:** Each channel's source and destination address registers can have configurable indexes for each read and write transfer. The address may remain constant, increment, decrement, or be adjusted by a programmable value. The programmable value allows a distinct index for the last transfer in a frame and for the preceding transfers. This feature is used for multichannel sorting.
- **Full-address 32-bit address range:** The DMA can access any region in the memory map:
  - The on-chip data memory.
  - The on-chip program memory when mapped into memory space.
  - The on-chip peripherals.
  - The external memory interface (EMIF).
- **Programmable-width transfers:** Each channel can be independently configured to transfer either bytes, 16-bit halfwords, or 32-bit words.
- **Autoinitialization:** Once a block transfer is complete, a DMA channel may automatically reinitialize itself for the next block transfer.
- **Event synchronization:** Each read, write, or frame transfer may be initiated by selected events.
- **Interrupt generation**: On completion of each frame transfer or of an entire block transfer, as well as on various error conditions, each DMA channel may send an interrupt to the CPU.

4.2 Enhanced Direct Memory Access (EDMA)

Device: ’C6211

The enhanced direct memory access (EDMA) controller, like the DMA controller, transfers data between regions in the memory map without intervention by the CPU. The EDMA allows movement of data to and from internal memory, internal peripherals, or external devices to occur in the background of CPU operation. The EDMA has sixteen independently programmable channels allowing sixteen different contexts for operation.

In addition to the features of the DMA controller, the EDMA also has the following features:

- **Sixteen channels:** The EDMA can keep track of the contexts of sixteen independent transfers.
- **Linking:** Each EDMA channel can be linked to a subsequent transfer to perform after completion.
- **Event synchronization:** Each channel is initiated by a specific event. Transfers may be either synchronized by element or by frame.

4.3 Host-Port Interface (HPI)

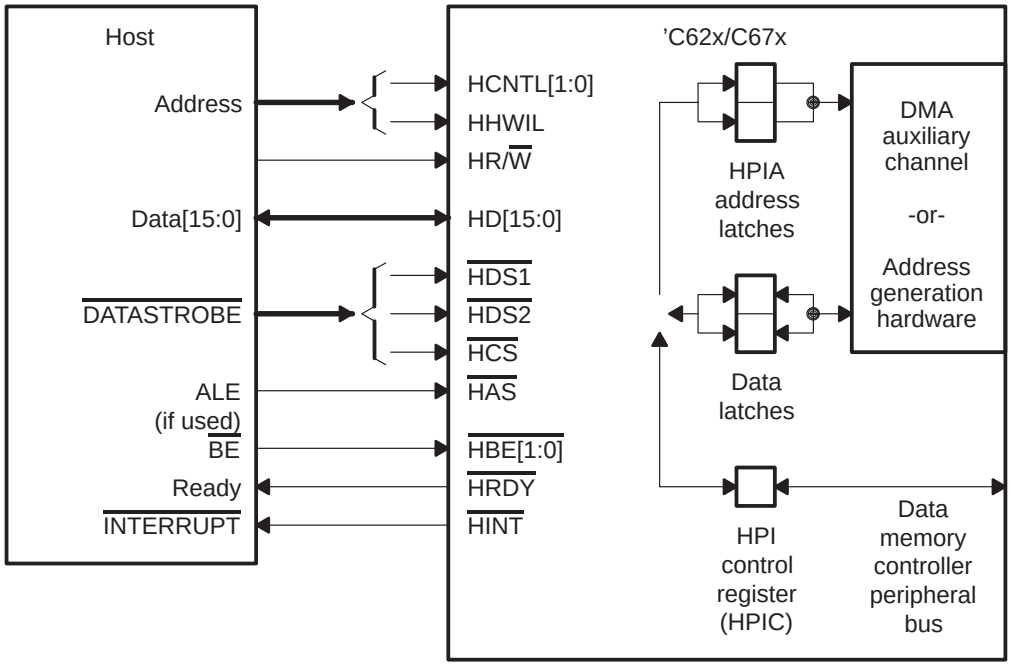
Devices: ’C6201, ’C6211, and ’C6701

The Host-Port Interface (HPI) is a 16-bit wide parallel port through which a host processor can directly access the CPU’s memory space. The host device functions as a master to the interface, which increases ease of access. The host and CPU can exchange information via internal or external memory. The host also has direct access to memory-mapped peripherals.

The HPI is connected to the internal memory via a set of registers. Either the host or the CPU may use the HPI Control register (HPIC) to configure the interface. The host can access the host address register (HPIA) and the host data register (HPID) to access the internal memory space of the device. The host accesses these registers using external data and interface control signals. The HPIC is a memory-mapped register, which allows the CPU access.

Connectivity to the CPU’s memory space is provided through the DMA controller for the ’C6201 and ’C6701. An auxiliary channel exists which performs data transfers to and from the host interface. On the ’C6211 the data transactions are performed within the EDMA, and are invisible to the user. Figure 4–1 is a simplified diagram of the interface between the host and the ’C62x/C67x HPI.

Figure 4–1. Host-port Interface (HPI) Block Diagram



The HPI provides 32-bit data to the CPU with an economical 16-bit external interface by automatically combining successive 16-bit transfers. The 16-bit data bus, HD[15:0], exchanges information with the host. On host data (HPID) write accesses, the $\overline{\text{HBE}}$[1:0] byte enables select the bytes in a 16-bit halfword are being written. For HPIA, HPIC, and HPID read accesses the byte enables are not used. The dedicated HHWIL pin indicates whether the first or second halfword is being transferred. An internal control register bit determines whether the first or second halfword is placed into the most significant halfword of a word.

The two data strobes ($\overline{\text{HDS1}}$ and $\overline{\text{HDS2}}$), the read/write select (HR/$\overline{\text{W}}$), and the address strobe ($\overline{\text{HAS}}$) enable the HPI to interface to a variety of industry-standard host devices with little or no additional logic required. The HPI can easily interface to hosts with either multiplexed or dedicated address and data lines.

The host can access HPID with an optional automatic address increment of HPIA. This feature facilitates reading or writing to sequential word locations.

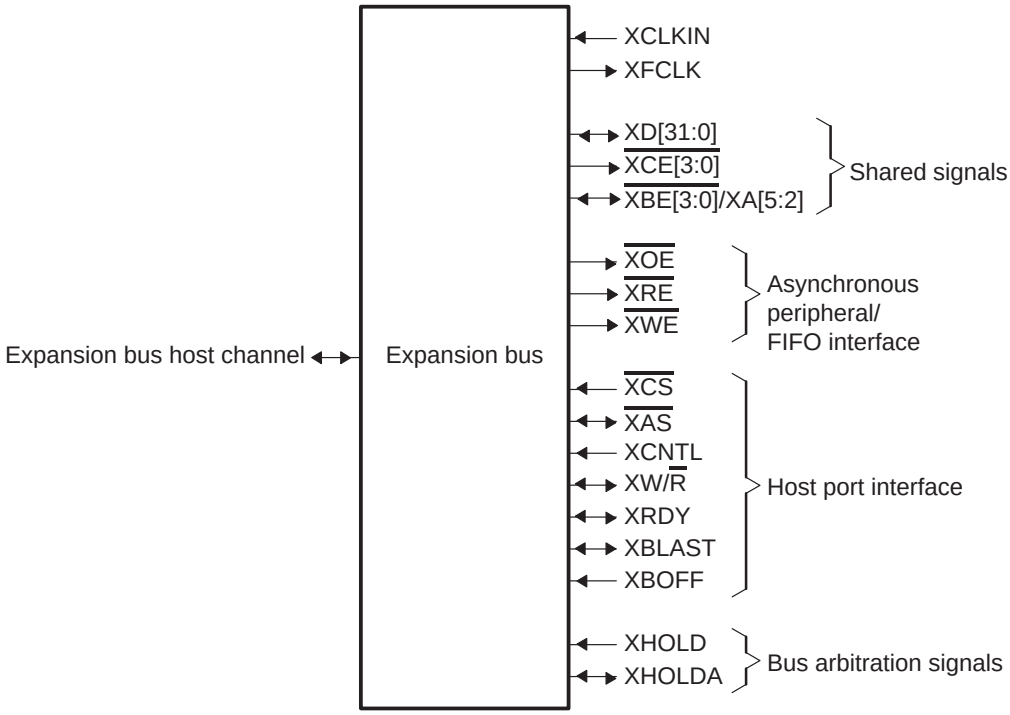
The HPI ready pin ($\overline{\text{HRDY}}$) allows insertion of host wait states. Wait states may be necessary depending on the latency of the memory accessed via the HPI, as well as on the rate of host access.

4.4 Expansion Bus (XB)

Device: ’C6202

The expansion bus on the ’C6202 serves as a replacement for the HPI and a complement of the external memory interface (EMIF). With the second bus for I/O devices, the EMIF loading may be reduced and data throughput may be increased. Allowing a 32-bit asynchronous host interface, as well as a synchronous interface to several bus types expands the HPI capability. The expansion bus is illustrated in Figure 4–2.

Figure 4–2. Expansion Bus



The expansion bus provides the device with an increased data throughput. The EMIF and the expansion bus are independant of one another, allowing concurrent accesses to both ports. An example of this would be the CPU running from SDRAM (EMIF) in cache mode, with the DMA servicing a host and I/O peripherals (expansion bus).

Allowing a second bus for I/O devices reduces the EMIF loading by splitting the number of external devices between two ports. The total bandwidth of the

memory interfaces is increased, as transfers to and from the EMIF will not need to be interrupted by peripheral or host servicing. The expansion bus also allows high-speed memories to be decoupled from lower speed devices.

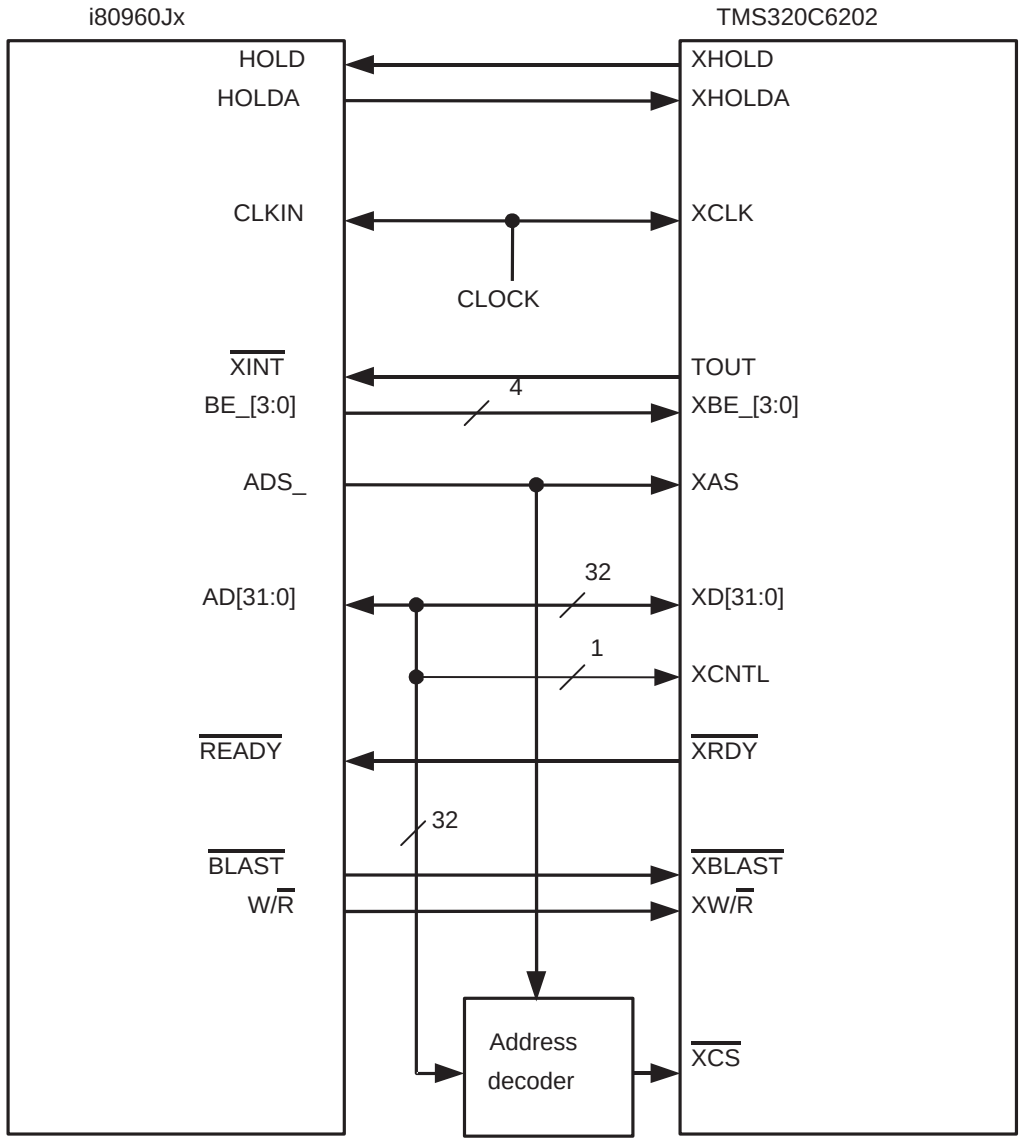
The host-interface capability of the device is improved over the HPI. The expansion bus offers two modes of operation: synchronous host and asynchronous host. The asynchronous host mode is a 32-bit version of the HPI. The synchronous mode allows an interface to several protocols:

- Master/slave PCI bridge interface
- Master/slave synchronous industry-standard host bus protocol

The expansion bus is serviced by the auxiliary channel of the DMA, and provides a high data-transfer rate.

An example of a synchronous master/slave interface is shown in Figure 4–3, in which the device is interfaced to a i80960Jx chip.

Figure 4–3. Synchronous Interface



4.5 External Memory Interface (EMIF)

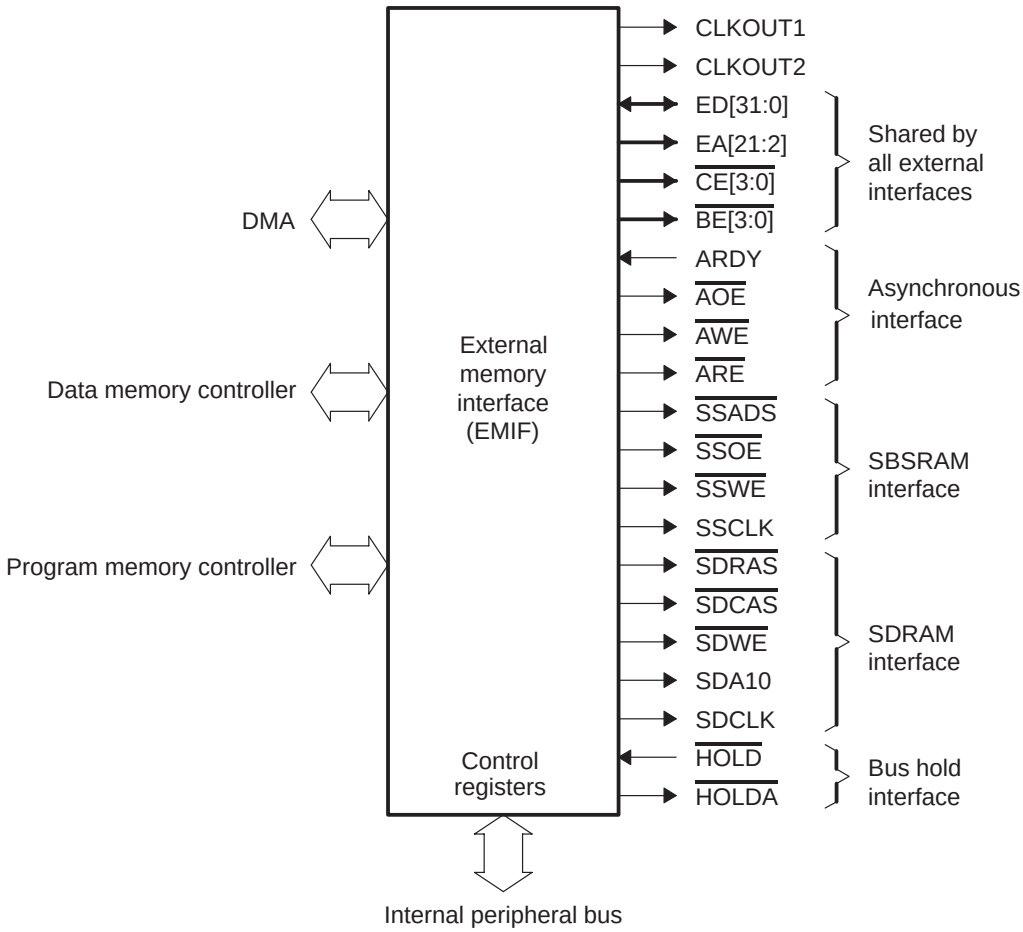
Devices: all

The external memory interface (EMIF) supports a glueless interface to several external devices, allowing additional data and program memory space beyond that which is included on-chip. The types of memories supported include:

- Synchronous burst SRAM (SBSRAM)
- Synchronous DRAM (SDRAM)
- Asynchronous devices, including asynchronous SRAM, ROM, and FIFOs. The EMIF provides highly programmable timings to these interfaces.
- External shared-memory devices

The EMIF is illustrated in Figure 4–4. Note that different devices of the ’C6000 platform may combine some signals, and that you should consult the data sheet for a specific pin listing of the EMIF.

Figure 4–4. External Memory Interface (EMIF) Block Diagram

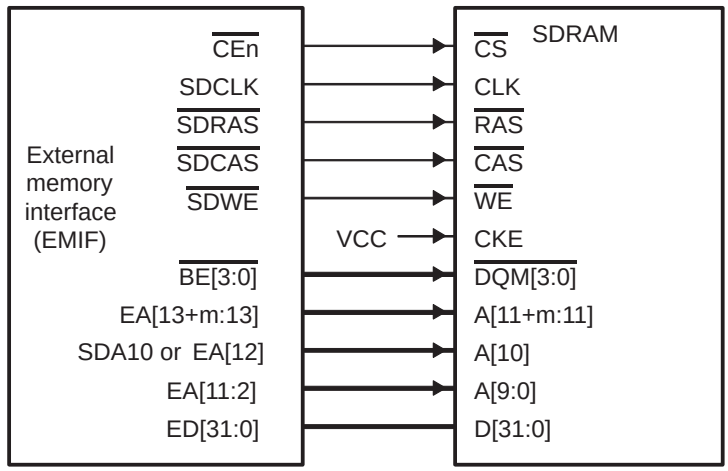


4.5.1 SDRAM Interface

The EMIF supports several different SDRAM configurations, which offers system designers an interface to high-speed and high-density memory. Figure 4–5 illustrates the EMIF to SDRAM interface. The EA pins starting from pin13 connect to the SDRAM address pins starting at pin 11. The symbol m is 0 for a 16M-bit interface and 2 for 64M-bit interface.

The SDRAM control pins are latched by the SDRAM on the rising SDCLK edge to determine the current operation. These signals are valid only if the chip select line for the SDRAM is low.

Figure 4–5. EMIF to SDRAM Interface

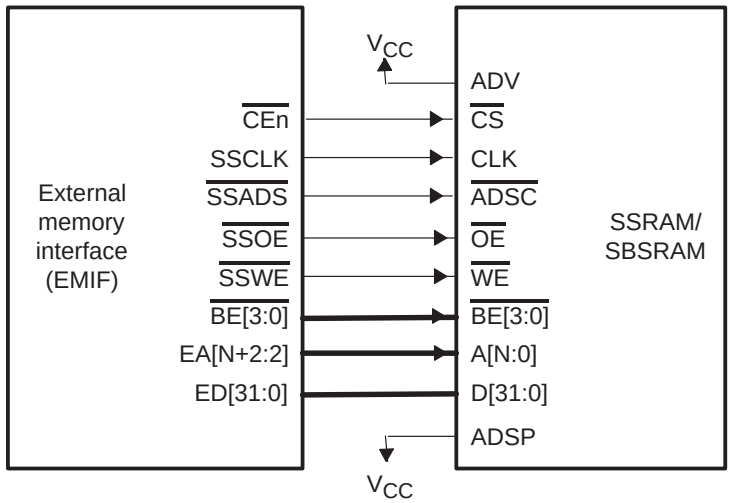


4.5.2 SBSRAM Interface

The EMIF interfaces directly to industry-standard synchronous burst SRAMs, as shown in Figure 4–6. This memory interface allows a high-speed memory interface without some of the limitations of SDRAM. Since SBSRAMs are SRAM devices, random accesses are possible during burst reads or writes. The SBSRAM interface can run at either the CPU clock speed or at half of this rate.

The four SBSRAM control pins are latched by the SBSRAM on the rising SSCLK edge to determine the current operation. These signals are valid only if the chip select line for the SBSRAM is low.

Figure 4–6. EMIF to SBSRAM Interface



4.5.3 Asynchronous Interface

The asynchronous interface offers configurable cycle types, which can be used to interface to a variety of memory and peripheral types, including SRAM, EPROM, and flash memory, as well as FPGA and ASIC devices.

The following three figures show interfaces to SRAM (Figure 4–7), to FIFOs (Figure 4–8), and to ROM (Figure 4–9).

Figure 4–7. EMIF to SRAM Interface

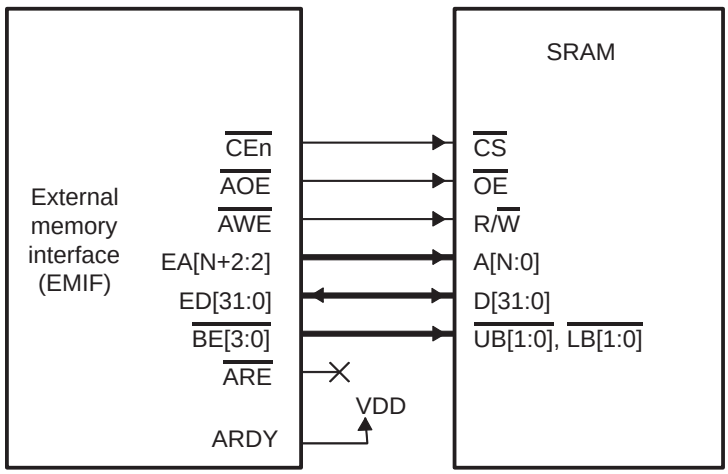


Figure 4–8. EMIF to FIFO Interface

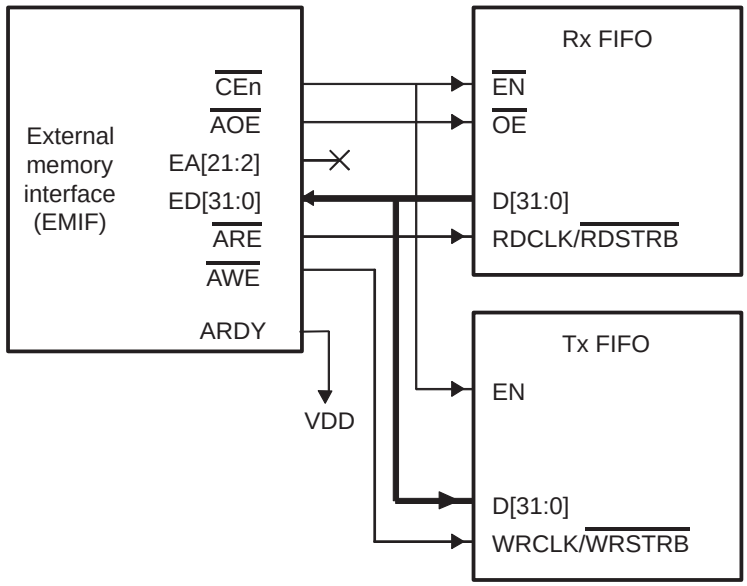

Figure 4–9. EMIF to ROM Interface

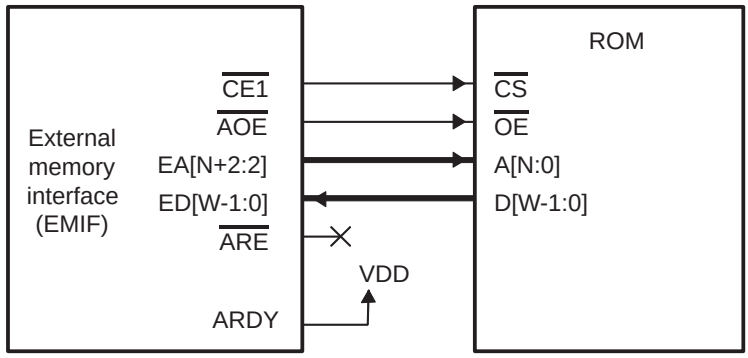


The EMIF supports 8-, 16-, and 32-bit wide ROMs. In Figure 4–8, the W denotes the number of data bits of the ROM. The memory-type field in the CE space control register selects the access modes. In reading data from these narrow-width memory spaces, the EMIF packs multiple reads into one 32-bit wide value. This mode is primarily intended for word access to 8-bit and 16-bit ROM devices.

For more specific memory interface descriptions, see the data sheet for the particular ’C6000 device, as well as the *TMS320C6201/C6701 Peripherals Reference Guide* and the *TMS320C6202/C6211 Peripherals Reference Guide Addendum.*

4.6 Boot Configuration Logic

Devices: all

The ’C62x and ’C67x devices provide a variety of boot configurations for proper device initialization. These configurations determine what actions the ’C62x/C67x performs after device reset to prepare for initialization. These boot configurations, which are set by external input pins, determine:

- The memory map the device selects. The memory map determines whether internal or external memory is mapped at address 0.
- The type of external memory at address 0 (if external memory is mapped at address 0)
- The boot process used to initialize the memory at address 0 before the CPU is allowed to run

4.6.1 Device Reset

The external device reset is the active-low $\overline{\text{RESET}}$ signal. While $\overline{\text{RESET}}$ is low, the device is held in reset. During this period the device is initialized to the prescribed reset state. All 3-state outputs are placed into the high-impedance state. All other outputs are returned to their default state. $\overline{\text{RESET}}$ is latched with the device CLKIN signal, as well as with the CPU clock. Thus, $\overline{\text{RESET}}$ has minimum low time in terms of CLKIN as well as CPU clock (CLKOUT1) cycles. The precise timing requirements for device reset are described in the data sheet for each particular device. The rising edge of $\overline{\text{RESET}}$ starts the processor running with the prescribed boot configuration.

4.6.2 Boot Configuration

External signals BOOTMODE[4:0] determine the boot configuration. The values of BOOTMODE[4:0] are latched with the rising edge of $\overline{\text{RESET}}$. Some ’C6000 devices provide separate pins for BOOTMODE[4:0], while some devices sample host port data lines HD[4:0] or expansion bus data lines XD[4:0]. These data lines are required to be pulled high or low using resistors to power/ground. The data sheet for the specific device will specifically state which signals determine the boot mode.

Three types of boot processes are available:

- **No boot process (direct-execution startup):** The CPU simply starts running from the memory located at address 0. When this memory location resides on SDRAM, the CPU is held until SDRAM initialization finishes. This mode is not supported on all ’C6000 devices.

- **ROM boot process:** A section of external memory is copied to address 0 by the DMA/EDMA controller. Although the boot process begins when the device is released from external reset, this transfer occurs while the CPU is held in reset internally. The amount of memory copied is 16K words of 32 bits each. The width of the ROM is selected by BOOTMODE[4:3]. In the case of ROM less than 32-bits wide, the EMIF can automatically pack consecutive 8-bit bytes or 16-bit halfwords to form the 32-bit instruction words to be moved. These values are expected to be stored in little-endian format in the external memory.

- **Host-boot process:** In the host-boot process, the CPU is held in reset while the remainder of the device is released from reset. During this period, an external host can initialize the CPU's memory space as necessary through the HPI or expansion bus, including external memory configuration registers. Once the necessary external memory has been configured, the host can access any external sections it needs to complete initialization. After all necessary initialization, the host writes a 1 to the DSPINT bit in the HPI control register (HPIC). This write causes an active transition on the DSPINT signal. In turn, this transition causes the boot configuration logic to remove the CPU from its reset state. The CPU then begins running from address 0. The CPU does not latch the DSPINT condition, because it occurs while the CPU is still in reset. Therefore the assertion will not register as an interrupt. Also, DSPINT wakes up the CPU from internal reset only if the HPI boot process is selected.

4.7 Multichannel Buffered Serial Port (McBSP)

Devices: all

The ’C62x/C67x multichannel buffered serial port (McBSP) is based on the standard serial port interface found on the TMS320C2000 and ’C5000 platforms. The standard serial port interface provides:

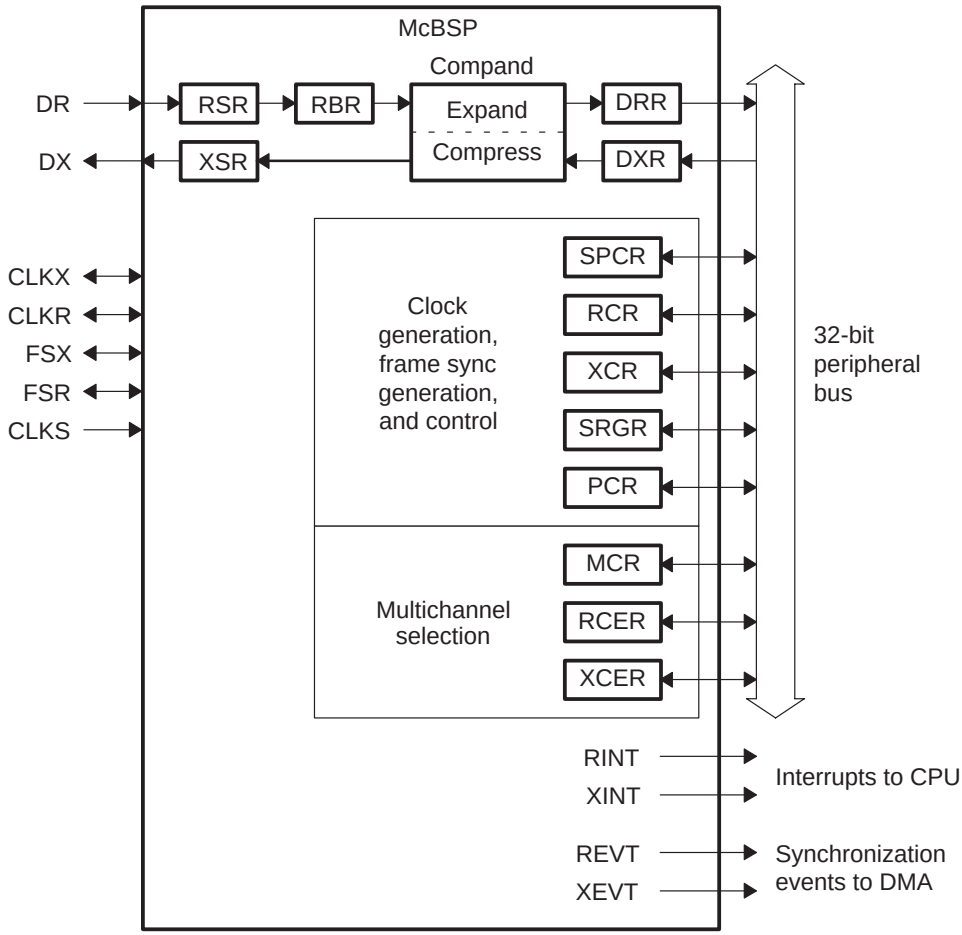
- ❏ Full-duplex communication
- ❏ Double-buffered data registers, which allow a continuous data stream
- ❏ Independent framing and clocking for reception and transmission
- ❏ Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices
- ❏ External shift clock generation or an internal programmable frequency shift clock

In addition, the McBSP has the following capabilities:

- ❏ Direct interface to:
  - T1/E1 framers
  - MVIP and ST-BUS compliant devices
  - IOM-2 compliant devices
  - AC97 compliant devices
  - IIS compliant devices
  - SPI™ devices
- ❏ Multichannel transmission and reception of up to 128 channels.
- ❏ A wider selection of element sizes including 8-, 12-, 16-, 20-, 24-, or 32-bit
- ❏ μ-Law and A-Law companding
- ❏ 8-bit data transfers with LSB or MSB first
- ❏ Programmable polarity for both frame synchronization and data clocks
- ❏ Highly programmable internal clock and frame generation

The McBSP consists of a data path and control path. Seven pins connect the control and data paths to external devices as shown in Figure 4–10.

Figure 4–10. Multichannel Buffered Serial Port (McBSP) Internal Block Diagram



Data is communicated to devices interfacing to the McBSP via the data transmit (DX) pin for transmission and the data receive (DR) pin for reception. Control information in the form of clocking and frame synchronization is communicated via CLKX, CLKR, FSX, and FSR. The peripheral device communicates to the McBSP via 32-bit-wide control registers accessible via the internal peripheral bus. The CPU or DMA controller reads the received data from the data receive register (DRR) and writes the data to be transmitted to the data transmit register (DXR). Data written to the DXR is shifted out to DX via the transmit shift register (XSR). Similarly, receive data on the DR pin is shifted into the receive shift register (RSR) and copied into the receive buffer register (RBR). RBR is then copied to DRR, which can be read by the CPU or the DMA controller. This allows internal data movement and external data communications simultaneously. The remaining registers accessible to the CPU configure the control mechanism of the McBSP. These registers are listed in Table 4–2. The

control block consists of internal clock generation, frame synchronization signal generation, control for both of these, and multichannel selection. This control block sends notification of important events to the CPU and the DMA controller via four signals as shown in Table 4–3.

Table 4–2. Multichannel Buffered Serial Port (McBSP) Registers

Abbreviation	Register Name
RBR	McBSP receive buffer register
RSR	McBSP receive shift register
XSR	McBSP transmit shift register
DRR	McBSP data receive register
DXR	McBSP data transmit register
SPCR	McBSP serial port control register
RCR	McBSP receive control register
XCR	McBSP transmit control register
SRGR	McBSP sample rate generator register
MCR	McBSP multichannel register
RCER	McBSP receive channel enable register
XCER	McBSP transmit channel enable register
PCR	McBSP pin control register

Table 4–3. Multichannel Buffered Serial Port (McBSP) CPU Interrupts and DMA Event Synchronization

Interrupt Name	Description
RINT	Receive interrupt to CPU
XINT	Transmit Interrupt to CPU
REVT	Receive synchronization event to DMA/EDMA
XEVT	Transmit synchronization event to DMA/EDMA

4.8 Timers

Devices: all

The ’C62x/C67x has two 32-bit general-purpose timers that you can use to:

- Time events
- Count events
- Generate pulses
- Interrupt the CPU
- Send synchronization events to the DMA controller

The timer has two signaling modes and can be clocked by an internal or an external source. The timer has an input pin (TINP) and an output pin (TOUT). The TINP pin can be used as a general-purpose input, and the TOUT pin can be used as a general-purpose output.

With an internal clock, the timer can signal an external A/D converter to start a conversion, or it can trigger the DMA controller to begin a data transfer. With an external clock, the timer can count external events and interrupt the CPU after a specified number of events.

4.9 Interrupt Selector

Devices: all

The ’C62x/C67x peripheral set produces 16 interrupt sources. The CPU has 12 interrupts available for use. The interrupt selector allows you to choose which 12 of the 16 your system needs to use. The interrupt selector also allows you to effectively change the polarity of external interrupt inputs.

Table 4–4 lists the available interrupts.

Table 4–4. Peripheral Interrupts

Interrupt Selection Number	Interrupt Abbreviation	Interrupt Description
0000b	DSPINT	Host port host to DSP interrupt
0001b	TINT0	Timer 0 interrupt
0010b	TINT1	Timer 1 interrupt
0011b	SD_INT	EMIF SDRAM timer interrupt
0100b	EXT_INT4	External interrupt pin 4
0101b	EXT_INT5	External interrupt pin 5
0110b	EXT_INT6	External interrupt pin 6
0111b	EXT_INT7	External interrupt pin 7
1000b	DMA_INT0/EDMA_INT	DMA Ch0 interrupt / EDMA interrupt
1001b	DMA_INT1	DMA Ch1 interrupt
1010b	DMA_INT2	DMA Ch2 interrupt
1011b	DMA_INT3	DMA Ch3 interrupt
1100b	XINT0	McBSP 0 transmit interrupt
1101b	RINT0	McBSP 0 receive Interrupt
1110b	XINT1	McBSP 1 transmit interrupt
1111b	RINT1	McBSP 1 receive interrupt

4.10 Power-Down Logic

Devices: all

Most of the operating power of CMOS logic is dissipated during circuit switching, from one logic state to another. By preventing some or all of the chip's logic from switching, significant power savings can be realized without losing any data or operational context. Power-down mode PD1 blocks the internal clock inputs at the boundary of the CPU, preventing most of its logic from switching, effectively shutting down the CPU. Additional power savings are accomplished in power-down mode PD2, in which the entire on-chip clock structure (including multiple buffers) is halted at the output of the PLL. Power-down mode PD3 shuts down the entire internal clock tree (like PD2) and also disconnects the external clock source (CLKIN) from reaching the PLL. Wake-up from PD3 takes longer than wake-up from PD2 because the PLL needs to be relocked, just as it does following power up.

PD2 and PD3 assert the PD pin for external recognition of these two power-down modes. In addition to power-down modes, the IDLE instruction provides lower CPU power consumption by executing multiple NOPs. The IDLE instruction terminates only upon servicing an interrupt.

Chapter 5

Development Support

The TMS320C62x and TMS320C67x design environment reflects the unique nature of the advanced VLIW architecture. The environment includes code generation tools, evaluation tools, documentation, online help with various tools, and a web site on the Internet (http://www.ti.com/sc/docs/dsps/products/C6000) with complete technical documentation.

Topic **Page**

5.1 Code Generation Tools

A complete development tool set for both the PC and Sun workstations includes the following:

- C compiler
- Assembly optimizer
- Assembler
- Linker
- Evaluation tools

The environment is founded on the generation's highly advanced C compiler and TI's revolutionary assembly optimizer. Figure 5–1 shows a flow of the process to develop code.

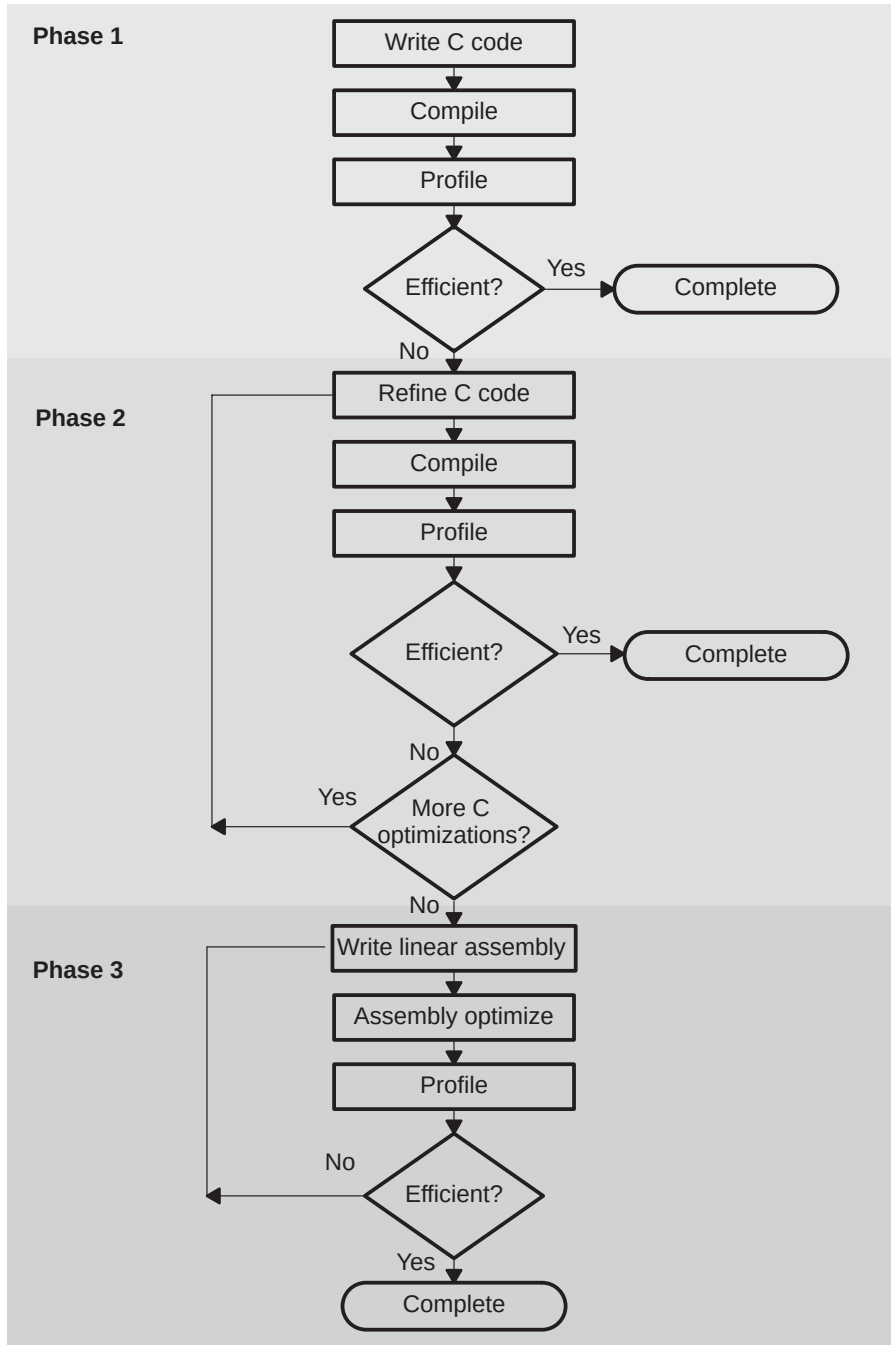
The 'C6000 platform's C compiler eliminates the need for extensive knowledge of DSP architecture, allowing you to take full advantage of the world's most powerful DSP. This highly-structured, architecture-independent C code development environment dramatically reduces development time for new products. At the same time, it maintains the inherent performance benefits of the advanced VLIW architecture. The 'C6000 compiler offers up to a 3X improvement in efficiency over existing fixed-point C compilers for DSP.

For application code sections that require the fine-tuning of assembly code, the 'C6000 platform's unique assembly optimizer provides the same transparent programming capability as the C compiler. The tool supports automatic scheduling, optimizing, and separation of fine-grained parallel tasks from linear assembly code, delivering a level of simplicity and power that is unprecedented in assembly-level tools.

The tools take C or assembly source code and implement many different optimizations, including software pipelining, to intelligently find and exploit the unique instruction-level parallelism of the 'C6000. After each step in the process, the 'C6000 tools allow you to evaluate their results and take appropriate steps to achieve the highest level of parallelism in your code.

Initially, all C code — new or reused from other applications — is run through the C compiler for the 'C6000. Using the evaluation tools described in the following section, you can evaluate the code for efficiency. If the performance is sufficient for the particular application, then the application has been completed, achieving the fastest possible time-to-market and incurring minimal engineering cost.

Figure 5–1. Code Development Flow Chart



A designer who needs to improve code efficiency can use intrinsics, command-line options, and source-code enhancements:

- The 'C6000 design tools feature two sets of intrinsics. The first set includes intrinsics that perform DSP-specific operations that are not supported directly in C. The second set is designed to facilitate 16-bit operation on a 32-bit machine. These intrinsic functions can be invoked to tune the performance of the C code. Some of the most commonly used intrinsics are described in Table 5–1.

Table 5–1. Selected TMS320C6000 C Compiler Intrinsics

C Compiler Intrinsic	Assembly Instruction	Description
uint **_clr(**uint *src2,* uint *csta*, uint *cstb***);**	**CLR**	Clears the specified field in src2. The beginning and ending bits of the field to be cleared are specified by csta and cstb, respectively.
int **_ext(**uint *src2,* uint *csta*, int *cstb***);**	**EXT**	Extracts the specified field in src2, sign-extended to 32 bits. The extract is performed by a shift left followed by a signed shift right; csta and cstb are the shift left and shift right amounts, respectively.
uint **_lmbd(**uint s*rc1,* uint *src2***);**	**LMBD**	Searches for a leftmost 1 or 0 of src2 determined by the LSB of src1. Returns the number of bits up to the value change.
int **_mpy(**int *src1,* int *src2***);**	**MPY**	Multiplies the 16 LSBs of src1 by the 16 LSBs of src2 and returns the result. Values can be signed or unsigned.
int **_sadd(**int *src1,* int *src2***);**	**SADD**	Adds src1 to src2 and saturates the result. Returns the result.
uint **_set(**uint *src2,* uint *csta*, uint *cstb***);**	**SET**	Sets the specified field in src2 to all 1s and returns the src2 value. The beginning and ending bits of the field to be set are specified by csta and cstb, respectively.
uint **_subc(**uint *src1,* uint *src2***);**	**SUBC**	Conditional subtract divide step

- You can experiment with several command-line options that cause the compiler to perform more aggressive optimization. One particularly useful option instructs the compiler to compile an entire application at once, giving the compiler visibility across program sections and more knowledge of the way in which variables and functions are used. Another option causes the compiler to perform global optimizations across an entire application.

- Source-code enhancements can be made to exploit specific features of the ’C6000 architecture. For example, the ’C62x has support for operating on words containing two 16-bit quantities; therefore, you can use 32-bit loads and stores when operating on arrays containing 16-bit data and easily achieve a 2X performance improvement.

Taken together, these actions result in a large amount of parallelism in C code.

For ultra-high performance applications, extracting every last bit of throughput from the application code may be necessary. The profiler can identify critical code segments that might benefit most from being generated in assembly language.

For these program sections, you write simple, linear ’C6000 assembly code that is input to the assembly optimizer. This assembly code is ’C6000 instructions written without concern for parallel instructions, instruction latencies, or register usage.

The assembly optimizer tool schedules the instructions, taking into account the architectural parallelism. The tool honors ’C6000 latency requirements, maximizes parallel code, and performs register allocation.

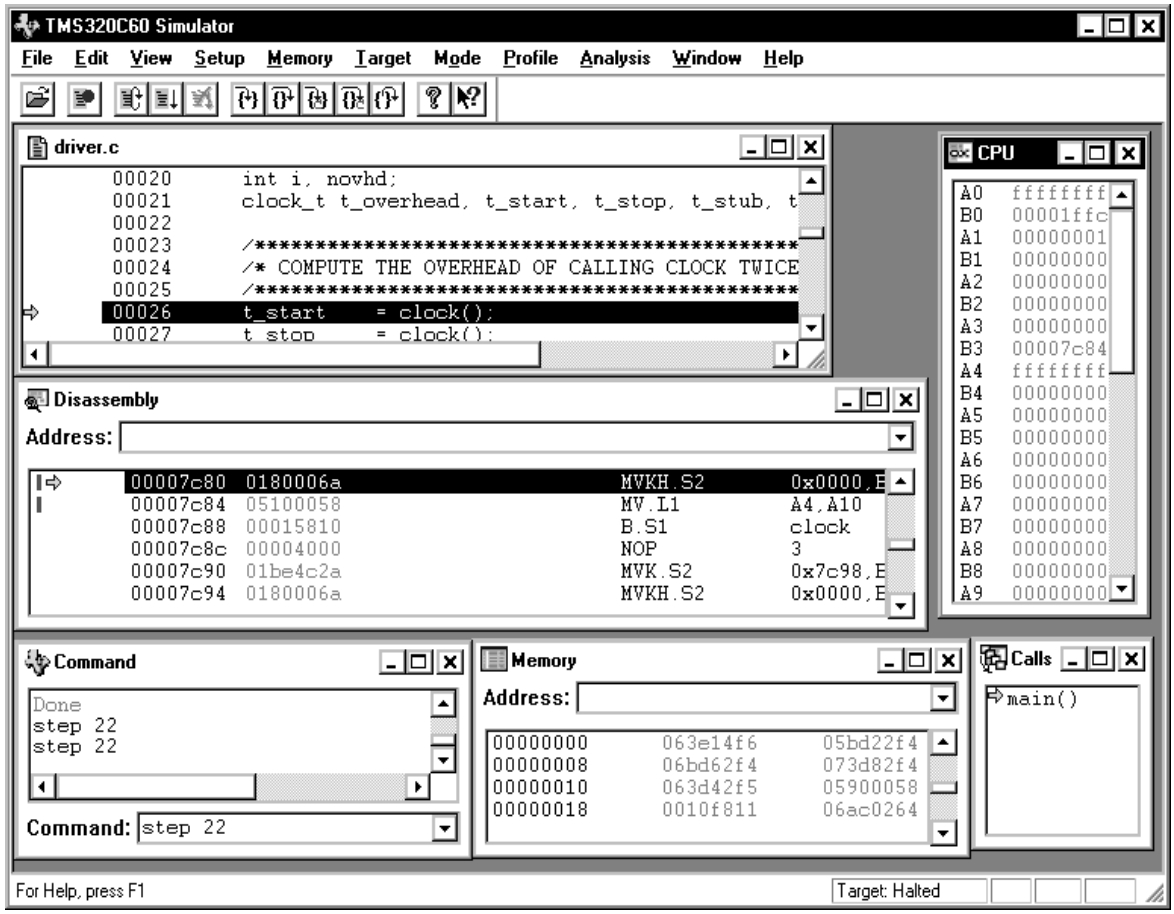
5.2 Evaluation Tools

The evaluation tools include the following items:

- ❑ Windows debugger interface
- ❑ Simulator
- ❑ Hardware emulation board

The ’C6000 development environment provides a new, intuitive Windows-based graphical user interface (GUI) for debugging. The debugger interface features windows for source, assembly, the call stack, memory, registers, and watch expressions, as well as menu and tool bars. The debugger offers one-click breakpoint setting and dialogs for editing breakpoints. The debugger also incorporates a dynamic profiler to help you find bottlenecks and improve code efficiency. Figure 5–2 shows the C debugger’s basic Windows interface.

Figure 5–2. Windows C Debugger Interface



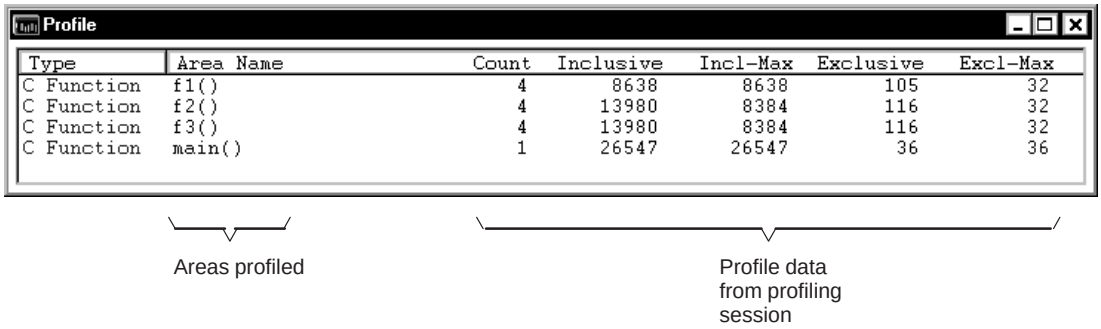
TI provides ’C6000 scan-based emulation systems that support hardware and software debugging of target systems via a JTAG-emulation cable. Scan-based emulation is a unique, nonintrusive approach to system emulation, integration, and debugging.

Initially, TI is offering a PC plug-in evaluation module (EVM) board, a low-cost PC-based board that is well-suited for software algorithm development. The EVM interfaces with a host platform through the XDS510™ and XDS510WS™ emulators through the IEEE Standard 1149.1 (JTAG)-compliant port. The board features a prototyping area for adding user-defined peripherals. With the addition of other ’C6000 platform members, TI will continually add functionality to the common development environment.

The dynamic profiler integrated into the ’C6000 debugger creates cycle histograms that are continuously updated as the code runs. It can show graphically which functions, ranges, and lines in an application are performance bottlenecks.

The statistics collected during a profiling session are displayed in the Profile window. Figure 5–3 shows an example of this window.

Figure 5–3. An Example of the Profile Window



You can modify the Profile window to display selected profile areas or different data; you can also sort the data differently.

A timing display can be built into the application by inserting a few function calls in the code. The resulting simple cycle counts, obtained without using the profiler or the debugger, can be printed automatically to allow you to track the changes in execution speed of an algorithm over time. This output, while less sophisticated, is continuously available with no further action.

5.3 Third-Party Support

TI has a long history of strong third-party support and this continues with the ’C62x/C67x devices. Table 5–2 lists the third-party contacts supporting the ’C62x/C67x devices and their product areas with telephone numbers and electronic mail addresses. For other contacts see out web site http://www.ti.com/sc/docs/dsps/develop/3party.htm

5.4 Web Site and Documentation

Visit the web site at http://www.ti.com/sc/docs/dsps/products/C6000 for information, an interactive multimedia technical overview (MeTO), documentation, and a schedule of 'C6000 design workshops. MeTO describes features of the devices in a visual way, with graphics in a point-and-click display for ease of navigation. The web site offers a complete training schedule of design workshops and seminars. Applications assistance and frequently asked questions (FAQ) are also on the web site.

Documentation is available directly from the web site in downloadable files for printing. There is a complete list of documentation available in this book's *Preface* under *Related Documentation From Texas Instruments*.

Appendix A

Glossary

A

address: The location of program code or data stored; an individually accessible memory location.

ALU: See *arithmetic logic unit.*

application-specific integrated circuit (ASIC): A custom chip designed for a specific application. It is designed by integrating standard cells from a library.

arithmetic logic unit (ALU): The hardware of the CPU that performs arithmetic and logic functions.

assembler: A software program that creates a machine-language program from a source file that contains assembly language instructions, directives, and macro definitions. The assembler substitutes absolute operation codes or relocatable codes for symbolic addresses.

assembly optimizer: A software program that optimizes linear assembly code, which is assembly code that has not been register-allocated or scheduled. The assembly optimizer is automatically invoked with the shell program, cl6x, when one of the input files has an .sa extension.

ASIC: See *application-specific integrated circuit.*

B

boot: The process of loading a program into memory.

boot configuration: A set of parameters defining how a device is booted.

boot loader: A built-in segment of code that transfers code from an external source to program memory at power up.

C

cache: A fast storage buffer in the central processing unit of a computer.

central processing unit (CPU): The unit that coordinates the functions of a processor.

circular addressing: An address mode in which a finite set of addresses is reused by linking the largest address back to the smallest address.

clock cycles: A periodic or sequence of events based on the input from the external clock.

code: A set of instructions written to perform a task; a computer program or part of a program.

compiler: A computer program that translates programs in a high-level language into their assembly-language equivalents.

control register: A register that contains bit fields which define the way a device operates.

control register file: A set of control registers.

CPU: See *central processing unit.*

crosspath: A link between register files to provide communication between the CPU units.

D

data memory: A region of memory used for storing or manipulating data, separate from the region used for storing program code.

direct memory access (DMA): Memory access that does not use the CPU; used for data transfer directly between memory and a peripheral.

direct memory access (DMA) controller: Specialized circuitry that transfers data from memory to memory without using the CPU.

DMA: See *direct-memory access.*

DRAM: See *dynamic random-access memory.*

dynamic random-access memory (DRAM): Memory that can be read and written by the microprocessor and whose storage locations can be accessed in any order but must be refreshed (recharged) periodically to retain data or program code.

E

E1: A European high-speed network communication service that operates at 2.048M bits per second and uses A-law companding.

erasable programmable read-only memory (EPROM): A memory device whose contents are erasable (usually via UV light) and programmable.

execute packet: A group of instructions that execute in parallel.

external interrupt: A hardware interrupt triggered by a pin.

external memory interface (EMIF): Microprocessor hardware which is used to read from and write to off-chip memory.

F

field programmable gate array (FPGA): An integrated circuit that contains an array of gates that can be programmed after manufacture, typically at the time of installation.

first-in, first-out (FIFO): A method for managing a set of items to which additions and deletions are made; items are added to one end of the list and removed from the other.

fixed-point processor: A processor which does arithmetic operations using integer arithmetic with no exponents.

flash memory: Electronically erasable, programmable nonvolatile (read-only) memory.

floating-point processor: A processor capable of handling floating-point arithmetic where real operands are represented using exponents.

G

global interrupt enable bit (GIE): A bit in the control status register (CSR) that is used to enable or disable maskable interrupts.

H

halfword: For this device, a halfword is defined as a 16-bit data item taken as a unit.

hardware interrupt: An interrupt triggered through physical connections with on-chip peripherals or external devices.

host port interface (HPI): A parallel interface that the CPU uses to communicate with a host processor.

I

indirect addressing: An addressing mode in which an address points to another pointer rather than to the actual data; this mode is prohibited in RISC architecture.

instruction fetch packet: A group of up to eight instructions held in memory for execution by the CPU.

interrupt: A signal sent by hardware or software to request a processor's attention. An interrupt tells the processor to suspend its current operation, save the current task status, and perform a particular set of instructions. Interrupts communicate with the operating system and prioritize tasks to be performed.

interrupt service fetch packet (ISFP): A fetch packet used to service interrupts. If eight instructions are insufficient, the user must branch out of this block for additional interrupt servicing. If the delay slots of the branch do not reside within the ISFP, execution continues from execute packets in the next fetch packet (the next ISFP).

L

latency: The delay between the occurrence of a condition and the reaction of the device. Also, in a pipeline, the necessary delay between the execution of two potentially conflicting instructions to ensure that the values used by the second instruction are correct.

least significant bit (LSB): The lowest order bit in a word.

M

maskable interrupt: A hardware interrupt that can be enabled or disabled through software.

million instructions per second (MIPS): A measure of the execution speed of a computer.

most significant bit (MSB): The highest order bit in a word.

multichannel buffered serial port (McBSP): An on-chip full-duplex circuit that provides direct serial communication through several channels to external serial devices.

multiplexer: A device for selecting one of several available signals.

multiplier: A CPU component that multiplies the contents of two registers.

multivendor internet protocol: A standard network protocol supported by several major network communication vendors.

N

nonmaskable interrupt (NMI): An interrupt that can be neither masked nor disabled.

normalization: The reduction of a complex data structure to its simplest form or of a circuit to its lowest number of gates.

O

overflow: A condition in which the result of an arithmetic operation exceeds the capacity of the register used to hold that result.

P

packing: Minimizing the space occupied by data or memory through the elimination of discontinuous spaces between segments.

parallelism: Sequencing events to occur simultaneously. Parallelism is achieved in a CPU by using instruction pipelining.

peripheral: A device connected to and usually controlled by a host device.

pipeline: A method of executing instructions in which the output of one process serves as the input to another, much like an assembly line. These processes become the stages or phases of the pipeline.

pipeline processing: A technique that provides simultaneous, or parallel, processing within the computer. It refers to overlapping operations by moving data or instructions into a conceptual pipe with all stages of the pipe processing simultaneously.

phase-locked loop (PLL): A circuit for synchronizing a variable oscillator with the phase of the transmitted signal.

program cache: A fast memory cache for storing program instructions allowing for quick execution.

program fetch unit: The CPU hardware that retrieves program instructions.

program memory: A memory region used for storing and executing programs, separate from the region used for storing data.

R

random-access memory (RAM): A type of memory device in which the individual locations can be accessed in any order.

register: A small area of high speed memory, located within a processor or electronic device, that is used for temporarily storing data or instructions. Each register is given a name, contains a few bytes of information, and is referenced by programs.

reduced-instruction set computer (RISC): A computer whose instruction set and related decode mechanism are much simpler than those of microprogrammed complex instruction set computers. The result is a higher instruction throughput and a faster real-time interrupt service response from a smaller, cost-effective chip.

reset: A means of bringing the CPU to a known state by setting the registers and control bits to predetermined values and signaling execution to start at a specified address.

S

saturation: A state where any further input no longer results in the expected output.

synchronous burst static random-access memory (SBSRAM): RAM whose content does not have to be refreshed periodically. Transfer of data is at a fixed rate relative to the clock speed of the device.

synchronous dynamic random-access memory (SDRAM): RAM whose content is refreshed periodically to prevent loss of the data. Transfer of data is at a fixed rate relative to the clock speed of the device.

shifter: A hardware unit that shifts bits in a word to the left or to the right.

T

T1: An American high-speed network communication service that runs at 1.544M bits per second and uses μ-law companding.

V

VelociTI: Architecture developed by TI that features very long instruction words.

VLIW: Very long instruction word.

W

word: A set of bits (32 bits for the ’C6000 devices) that is stored, addressed, transmitted, or operated on as a unit.
